Day 1: Friday October 3, 2014

Surreal numbers were discovered by John Conway. The class of all surreal numbers is denoted **No** and this class comes equipped with a natural linear ordering and arithmetic operations making **No** a real closed ordered field.

For example, $1/\omega, \omega - \pi, \sqrt{\omega} \in \mathbf{No}$, where ω denotes the first infinite ordinal.

Theorem 0.1 (Kruskal, 1980s). *There is an exponential function $\exp: \mathbf{No} \rightarrow \mathbf{No}$ extending the usual exponential $x \mapsto e^x$ on \mathbb{R} .*

Theorem 0.2 (van den Dries-Ehrlich, c. 2000). $(\mathbb{R}, 0, 1, +, \cdot, \leq, e^x) \preceq (\mathbf{No}, 0, 1, +, \cdot, \leq, \exp)$.

1 Basic Definitions and Existence Theorem

Throughout this class, we will work in von Neumann-Bernays-Gödel set theory with global choice (NBG). This is conservative over ZFC (see Ehrlich, *Absolutely Saturated Models*).

An example of a surreal number is the following:

$$\begin{aligned} f: \{0, 1, 2\} &\longrightarrow \{+, -\} \\ 0 &\longmapsto + \\ 1 &\longmapsto - \\ 2 &\longmapsto + \end{aligned}$$

This may be depicted in tree form as follows: We will denote such a surreal number by $f = (+ - +)$. Another example is:

$$\begin{aligned} f: \omega + \omega &\longrightarrow \{+, -\} \\ n &\longmapsto + \\ \omega + n &\longmapsto - \end{aligned}$$

We write **No** for the class of surreal numbers. We often view $f \in \mathbf{No}$ as a function $f: \mathbf{On} \rightarrow \{+, -, 0\}$ by setting $f(\alpha) = 0$ for $\alpha \notin \text{dom}(f)$.

Definition 1.1. Let $a, b \in \mathbf{No}$.

1. We say that a is an *initial segment* of b if $l(a) \leq l(b)$ and $b \upharpoonright \text{dom}(a) = a$. We denote this by $a \leq_s b$ (read: “ a is simpler than b ”).
2. We say that a is a *proper initial segment* of b if $a \leq_s b$ and $a \neq b$. We denote this by $a <_s b$.
3. If $a \leq_s b$, then the *tail* of a in b is the surreal number c of length $l(b) - l(a)$ satisfying $c(\alpha) = a(l(b) + \alpha)$ for all α .
4. We define $a \frown b$ to be the surreal number satisfying:

$$(a \frown b)(\alpha) = \begin{cases} a(\alpha) & \alpha < l(a) \\ b(\alpha - l(a)) & \alpha \geq l(a) \end{cases}$$

(so in particular if $a \leq_s b$ and c is the tail of a in b , then $b = a \frown c$).

5. Suppose $a \neq b$. Then the *common initial segment* of a and b is the element $c \in \mathbf{No}$ with minimal length such that $a(l(c)) \neq b(l(c))$ and $c \upharpoonright l(c) = a \upharpoonright l(c) = b \upharpoonright l(c)$. We write $c = a \wedge b$, and also set $a \wedge a = a$.

Note that

$$a \leq_s b \iff a \wedge b = a$$

Day 2: Monday October 6, 2014

Definition 1.2. We order $\{+, -, 0\}$ by setting $- < 0 < +$ and for $a, b \in \mathbf{No}$ we define

$$\begin{aligned} a < b &\iff a < b \text{ lexicographically} \\ &\iff a \neq b \wedge a(\alpha_0) < b(\alpha_0) \text{ where } \alpha_0 = l(a \wedge b) \end{aligned}$$

As usual we also set $a \leq b \iff a < b \vee a = b$.

Clearly \leq is a linear ordering on \mathbf{No} .

Examples:

$$\begin{aligned} (+ - +) &< (+ + + \dots - - - \dots) \\ (- +) &< () < (+ -) < (+) < (++) \end{aligned}$$

Remark: if $a \leq_s b$ then $a \wedge b = a$ and if $b \leq_s a$ then $a \wedge b = b$. Suppose that neither $a \leq_s b$ or $b \leq_s a$. Put:

$$\alpha_0 = \min \{\alpha : a(\alpha) \neq b(\alpha)\}$$

Then either $a(\alpha_0) = +$ and $b(\alpha_0) = -$, in which case $b < (a \wedge b) < a$, or $a(\alpha_0) = -$ and $b(\alpha_0) = +$, in which case $a < (a \wedge b) < b$. In either case:

$$a \wedge b \in [\min \{a, b\}, \max \{a, b\}]$$

Definition 1.3. Let L, R be subsets (or subclasses) of \mathbf{No} . We say $L < R$ if $l < r$ for all $l \in L$ and $r \in R$. We define $A < c$ for $A \cup \{c\} \subseteq \mathbf{No}$ in the obvious manner.

Note that $\emptyset < A$ and $A < \emptyset$ for all $A \subseteq \mathbf{No}$ by vacuous satisfaction.

Theorem 1.4 (Existence Theorem). *Let L, R be subsets of \mathbf{No} with $L < R$. Then there exists a unique $c \in \mathbf{No}$ of minimal length such that $L < c < R$.*

Proof. We first prove existence. Let

$$\gamma = \sup_{a \in L \cup R} (l(a) + 1)$$

be the least strict upper bound of lengths of elements of $L \cup R$ (it is here that we use that L and R are sets rather than proper classes). For each ordinal α , denote by $L \upharpoonright \alpha$ the set $\{l \upharpoonright \alpha : l \in L\}$, and similarly for R . Note that $L \upharpoonright \gamma = L$ and $R \upharpoonright \gamma = R$. We construct c of length γ by defining the values $c(\alpha)$ by induction on $\alpha \leq \gamma$ as follows:

$$c(\alpha) = \begin{cases} - & \text{if } (c \upharpoonright \alpha \frown (-)) \geq L \upharpoonright (\alpha + 1) \\ + & \text{otherwise} \end{cases}$$

Claim 1.5. $c \geq L$

Proof of Claim. Otherwise there is $l \in L$ such that $c < l$. This means $c(\alpha_0) < l(\alpha_0)$ where $\alpha_0 = l(c \wedge l)$. Since $c(\alpha_0)$ must be in $\{-, +\}$ (i.e. is nonzero) this implies $c(\alpha_0) = -$ even though $(c \upharpoonright \alpha_0 \frown (-)) \not\geq l \upharpoonright (\alpha_0 + 1)$, a contradiction. \square

Claim 1.6. $c \leq R$

Proof of Claim. Otherwise there exists $r \in R$ such that $r < c$. This means $r(\alpha_0) < c(\alpha_0)$ where $\alpha_0 = l(r \wedge c)$. Since $c(\alpha_0) > r(\alpha_0)$, we must be in the “ $c(\alpha_0) = +$ ” case, and so there is some $l \in L$ such that $l \upharpoonright (\alpha_0 + 1) > (c \upharpoonright \alpha_0) \frown (-) = (r \upharpoonright \alpha_0) \frown (-)$. In particular $l(\alpha_0) \in \{0, +\}$. So if $r(\alpha_0) = -$ then $r < l$, and if $r(\alpha_0) = 0$ then $r \leq l$, in either case contradicting $L < R$. \square

At this point we have shown $L \leq c \leq R$. But by construction c has length γ , and so in particular cannot be an element of $L \cup R$. Thus

$$L < c < R$$

as desired. \square

Day 3: Wednesday October 8, 2014

Last time we showed that there is $c \in \mathbf{No}$ with $L < c < R$. The well-ordering principle on \mathbf{On} gives us such a c of minimal length. Let now $d \in \mathbf{No}$ satisfy $L < d < R$. Then $L < (c \wedge d) < R$. By minimality of $l(c)$ and since $(c \wedge d) \leq_s c$ we have $l(c \wedge d) = l(c)$. Therefore $(c \wedge d) = c$, or in other words $c \leq_s d$.

Notation: $\{L|R\}$ denotes the $c \in \mathbf{No}$ of minimal length with $L < c < R$. Some remarks:

- (1) $\{L|\emptyset\}$ consists only of $+$'s.
- (2) $\{\emptyset|R\}$ consists only of $-$'s.

Lemma 1.7. *If $L < R$ are subsets of \mathbf{No} , then*

$$l(\{L|R\}) \leq \min \{\alpha : l(b) < \alpha \text{ for all } b \in L \cup R\}$$

Conversely, every $a \in \mathbf{No}$ is of the form $a = \{L|R\}$ where $L < R$ are subsets of \mathbf{No} such that $l(b) < l(a)$ for all $b \in L \cup R$.

Proof. Suppose that α satisfies $l(\{L|R\}) > \alpha > l(b)$ for all $b \in L \cup R$. Then $c := \{L|R\} \upharpoonright \alpha$ also satisfies $L < c < R$, contradicting the minimality of $l(\{L|R\})$. For the second part, let $a \in \mathbf{No}$ and set $\alpha := l(a)$. Put:

$$\begin{aligned} L &:= \{b \in \mathbf{No} : b < a \text{ and } l(b) < \alpha\} \\ R &:= \{b \in \mathbf{No} : b > a \text{ and } l(b) < \alpha\} \end{aligned}$$

Then $L < a < R$ and $L \cup R$ contains all surreals of length $< \alpha = l(a)$. So $a = \{L|R\}$. \square

Definition 1.8. Let L, L', R, R' be subsets of \mathbf{No} . We say that (L', R') is *cofinal* in (L, R) if:

- $(\forall a \in L)(\exists a' \in L')$ such that $a \leq a'$, and
- $(\forall b \in R)(\exists b' \in R')$ such that $b \geq b'$.

Some trivial observations:

- If $L' \supseteq L$ and $R' \supseteq R$, then (L', R') is cofinal in (L, R) and in particular (L, R) is cofinal in (L, R) .
- Cofinality is transitive.
- If (L', R') is cofinal in (L, R) and $L' < R'$, then $L < R$.
- If (L', R') is cofinal in (L, R) and $L' < a < R'$, then $L < a < R$.

Theorem 1.9 (The “Cofinality Theorem”). *Let L, L', R, R' be subsets of \mathbf{No} with $L < R$. Suppose $L' < \{L|R\} < R'$ and (L', R') is cofinal in (L, R) . Then $\{L|R\} = \{L'|R'\}$.*

Proof. Suppose that $L' < a < R'$. Then $L < a < R$ since (L', R') is cofinal in (L, R) . Hence $l(a) \geq l(\{L|R\})$. Thus $\{L|R\} = \{L|R'\}$. \square

Corollary 1.10 (Canonical Representation). Let $a \in \mathbf{No}$ and set

$$\begin{aligned} L' &= \{b: b < a \text{ and } b <_s a\} \\ R' &= \{b: b > a \text{ and } b <_s a\} \end{aligned}$$

Then $a = \{L'|R'\}$.

Proof. By Lemma 1.7 take $L < R$ such that $a = \{L|R\}$ and $l(b) < l(a)$ for all $b \in L \cup R$. Then $L' \subseteq L$ and $R' \subseteq R$, so (L, R) is cofinal in (L', R') . By Theorem 1.9 it remains to show that (L', R') is cofinal in (L, R) .

For this let $b \in L$ be arbitrary. Then $l(a \wedge b) \leq l(b) < l(a)$ and thus $b \leq (a \wedge b) < a$. Therefore $a \wedge b \in L'$. Similarly for R . \square

Exercise: let $a = \{L'|R'\}$ be the canonical representation of $a \in \mathbf{No}$. Then

$$\begin{aligned} L' &= \{a \restriction \beta: a(\beta) = +\} \\ R' &= \{a \restriction \beta: a(\beta) = -\} \end{aligned}$$

Exercise: Let $a = \{L'|R'\}$ be the canonical representation of $a \in \mathbf{No}$. Then

$$\begin{aligned} L' &= \{a \restriction \beta: a(\beta) = +\} \\ R' &= \{a \restriction \beta: a(\beta) = 1\} \end{aligned}$$

For example, if $a = (+ + - + - - +)$, then $L' = \{(), (+), (+ + -), (+ + - + - -)\}$ and $R' = \{(++), (++ +), (++ + -), (++ + - -)\}$. Note that the elements of L' decrease in the ordering as their length increases, whereas those of R' do the opposite. Also note that the canonical representation is not minimal, as a may also be realized as the cut $a = \{(++ + - - -)|(++ + - -)\}$.

Corollary 1.11 (“Inverse Cofinality Theorem”). Let $a = \{L|R\}$ be the canonical representation of a and let $a = \{L'|R'\}$ be an arbitrary representation. Then (L', R') is cofinal in (L, R) .

Proof. Let $b \in L$ and suppose that for a contradiction that $L' < b$. Then $L' < b < a < R'$, and $l(b) < l(a)$, contradicting $a = \{L'|R'\}$. \square

2 Arithmetic Operators

We will define addition and multiplication on \mathbf{No} and we will show that they, together with the ordering, make \mathbf{No} into an ordered field.

Day 4: Friday, October 10, 2014

We begin by recalling some facts about ordinal arithmetic:

Theorem 2.1 (Cantor’s Normal Form Theorem). *Every ordinal α can be uniquely represented as*

$$\alpha = \omega^{\alpha_1} a_1 + \omega^{\alpha_2} a_2 + \cdots + \omega^{\alpha_n} a_n$$

where $\alpha_1 > \cdots > \alpha_n$ are ordinals and $a_1, \dots, a_n \in \mathbb{N} \setminus \{0\}$.

Definition 2.2. The (Hessenberg) *natural sum* $\alpha \oplus \beta$ of two ordinals

$$\begin{aligned} \alpha &= \omega^{\gamma_1} a_1 + \cdots + \omega^{\gamma_n} a_n \\ \beta &= \omega^{\gamma_1} b_1 + \cdots + \omega^{\gamma_n} b_n \end{aligned}$$

where $\gamma_1 > \cdots > \gamma_n$ are ordinals and $a_i, b_j \in \mathbb{N}$, is defined by:

$$a \oplus \beta = \omega^{\gamma_1} (a_1 + b_1) + \cdots + \omega^{\gamma_n} (a_n + b_n)$$

The operation \oplus is associative, commutative, and strictly increasing in each argument, i.e. $\alpha < \beta \implies \alpha \oplus \gamma < \beta \oplus \gamma$ for all $\alpha, \beta, \gamma \in \mathbf{On}$. Hence \oplus is *cancellative*: $\alpha \oplus \gamma = \beta \oplus \gamma \implies \alpha = \beta$. There is also a notion of *natural product* of ordinals:

Definition 2.3. For α, β as above, set

$$\alpha \otimes \beta := \bigoplus_{i,j} \omega^{\gamma_i \oplus \gamma_j} a_i b_j$$

The natural product is also associative, commutative, and strictly increasing in each argument. The distributive law also holds for \oplus, \otimes :

$$\alpha \otimes (\beta \oplus \gamma) = (\alpha \otimes \beta) \oplus (\alpha \otimes \gamma)$$

In general $\alpha \otimes \beta \geq \alpha + \beta$. Moreover strict inequality may occur: $1 \oplus \omega = \omega + 1 > \omega = 1 + \omega$.

In the following, if $a = \{L|R\}$ is the canonical representation of $a \in \mathbf{No}$, we set $L(a) = L$ and $R(a) = R$. We will use the shorthand $X + a = \{x + a : x \in X\}$ (and its obvious variations) for X a subset of \mathbf{No} and $a \in \mathbf{No}$.

Definition 2.4. Let $a, b \in \mathbf{No}$. Set

$$a + b := \{(L(a) + b) \cup (L(b) + a) | (R(a) + b) \cup (R(b) + a)\} \quad (1)$$

Some remarks:

- (1) This is an inductive definition on $l(a) \oplus l(b)$. There is no special treatment needed for the base case: $\{\emptyset|\emptyset\} = + \{\emptyset|\emptyset\} = \{\emptyset|\emptyset\}$.
- (2) To justify the definition we need to check that the sets L, R used in defining $a + b = \{L|R\}$ satisfy $L < R$.

Lemma 2.5. Suppose that for all $a, b \in \mathbf{No}$ with $l(a) \oplus l(b) < \gamma$ we have defined $a + b$ so that Equation 1 holds and

$$b > c \implies a + b > a + c \text{ and } b + a > c + a \quad (*)$$

holds for all $a, b, c \in \mathbf{No}$ with $l(a) \oplus l(b) < \gamma$ and $l(a) \oplus l(c) < \gamma$. Then for all $a, b \in \mathbf{No}$ with $l(a) \oplus l(b) \leq \gamma$ we have

$$(L(a) + b) \cup (L(b) + a) < (R(a) + b) \cup (R(b) + a)$$

and defining $a + b$ as in Equation 1, $(*)$ holds for all $a, b, c \in \mathbf{No}$ with $l(a) \oplus l(b) \leq \gamma$ and $l(a) \oplus l(c) \leq \gamma$.

Proof. The first part is immediate from $(*)$ in conjunction with the fact that $l(a_L), l(a_R) < l(a), l(b_L), l(b_R) < l(b)$ for all $a_L \in L(a), a_R \in R(a), b_L \in L(b)$, and $b_R \in R(b)$. Define $a + b$ for $a, b \in \mathbf{No}$ with $l(a) \oplus l(b) \leq \gamma$ as in Equation 1. Suppose $a, b, c \in \mathbf{No}$ with $l(a) \oplus l(b), l(a) \oplus l(c) \leq \gamma$, and $b > c$. Then by definition we have

$$\begin{aligned} a + b_L &< a + b \\ a + c &< a + c_R \end{aligned}$$

for all $b_L \in L(b)$ and $c_R \in R(c)$. If $c <_s b$ then we can take $b_L = c$ and get $a + b > a + c$. Similarly, if $b <_s c$, then we can take $c_R = b$ and also get $a + b > a + c$. Suppose neither $c <_s b$ nor $b <_s c$ and put $d := b \wedge c$. Then $l(d) < l(b), l(c)$ and $b > d > c$. Hence by $(*)$, $a + b > a + d > a + c$.

We may show $b + a > c + a$ similarly. □

Lemma 2.6 (“Uniformity” of the Definition of a and b). Let $a = \{L|R\}$ and $a' = \{L'|R'\}$. Then

$$a + a' = \{(L + a') \cup (a' + L) | (R + a') \cup (a + R')\}$$

Proof. Let $a = \{L_a | R_a\}$ be the canonical representation. By Corollary 1.11 (L, R) is cofinal in (L_a, R_a) and (L', R') is cofinal in $(L_{a'}, R_{a'})$. Hence

$$((L + a') \cup (a + L'), (R + a') \cup (a + R'))$$

is cofinal in

$$((L_a + a') \cup (a + L_{a'}), (R_a + a') \cup (a + R_{a'}))$$

Moreover,

$$(L + a') \cup (a + L') < a + a' < (R + a') \cup (a + R')$$

Now use Theorem 1.9 to conclude the proof. □

Week 2

Monday 10-13-2014

Let $a, b \in \mathbf{No}$. Recall that $a + b = \{a_L + b, a + b_L | a_R + b, a + b_R\}$.

Theorem 2.7. $(\mathbf{No}, +, <)$ is an ordered abelian group with $0 = () = \{\emptyset, \emptyset\}$ and $-a$ is obtained by reversing all signs in a .

Proof. We have already proven that \leq is translation invariant.

Commutativity is clear from the symmetric nature of the definition.

We show by induction on $l(a)$ that $a + 0 = a$. The base case is clear, and

$$\begin{aligned} a + 0 &= \{a_L + 0, a + 0_L | a_R + 0, a + 0_R\} \\ &= \{a_L + 0 | a_R + 0\} \text{ (as } 0_L = 0_R = \emptyset) \\ &= \{a_L | a_R\} \text{ (by induction)} \\ &= a \end{aligned}$$

We next show the associative law by induction on $l(a) \oplus l(b) \oplus l(c)$. We have

$$\begin{aligned} (a + b) + c &= \{(a + b)_L + c, (a + b) + c_L | (a + b)_R + c, (a + b) + c_R\} \\ &= \{(a_L + b) + c, (a + b_L) + c, (a + b) + c_L | (a_R + b) + c, (a + b_R) + c, (a + b) + c_R\} \end{aligned}$$

where the second equality holds because of uniformity. An identical calculation shows:

$$a + (b + c) = \{a_L + (b + c), a + (b_L + c), a + (b + c_L) | a_R + (b + c), a + (b_R + c), a + (b + c_R)\}$$

and hence $(a + b) + c = a + (b + c)$ holds by induction.

To show $a + (-a) = 0$ first note:

1. $b <_s a \Rightarrow -b <_s -a$
2. $b < a \Rightarrow -b > -a$

Hence, $-a = \{-a_R | -a_L\}$. Thus,

$$a + (-a) = \{a_L + (-a), a + (-a_R) | a_R + (-a), a + (-a_L)\}$$

By the induction hypothesis and the fact that $+$ is increasing we have the following:

1. $a_L + (-a) < a_L + (-a_L) = 0$
2. $a + (-a_R) < a_R + (-a_R) = 0$
3. $a_R + (-a) > a_R + (-a_R) = 0$
4. $a + (-a_L) > a_L + (-a_L) = 0$

Thus, 0 is a realization of the cut. Since 0 has minimal length, we have $a + (-a) = 0$ as needed. \square

Definition 2.8. For $a, b \in \mathbf{No}$ set

$$a \cdot b = \{a_L \cdot b + a \cdot b_L - a_L \cdot b_L, a_R \cdot b + a \cdot b_R - a_R \cdot b_R | a_L \cdot b + a \cdot b_R - a_L \cdot b_R, a_R \cdot b + a \cdot b_L - a_R \cdot b_L\}$$

As motivation for this definition, note that in any ordered field: if $a' < a, b' < b$ then $(a - a')(b - b') > 0$ so in particular $a'b + ab' - a'b' < ab$.

Lemma 2.9. Suppose for all $a, b \in \mathbf{No}$ with $l(a) \oplus l(b) < \gamma$ we have defined $a \cdot b$ so that (2.8) holds, and for all $a, b, c, d \in \mathbf{No}$ with the natural sum of the lengths of each factor is $< \gamma$ (*) holds, where $(*) : a > b, c > d \Rightarrow ac - bc > ad - bd$. Then: (2.8) holds for all $a, b \in \mathbf{No}$ with $l(a) \oplus l(b) \leq \gamma$ and (*) holds for all $a, b, c, d \in \mathbf{No}$ with the natural sum of the lengths of each factor is $\leq \gamma$.

Proof. Let $P(a, b, c, d) \Leftrightarrow ac - bc > ad - bd$. Because the surreal numbers form an ordered abelian group, P is "transitive in the last two variables" (i.e. $P(a, b, c, d) \& P(a, b, d, e) \Rightarrow P(a, b, c, e)$) and similarly in the first two variables.

Fix $a, b \in \mathbf{No}$. For $a' <_s a, b' <_s b$ we define $f(a', b') = a'b + ab' - a'b'$.

Claim:

1. $a' < a \Rightarrow b' \mapsto f(a', b')$ is an increasing function
2. $a' > a \Rightarrow b' \mapsto f(a', b')$ is a decreasing function
3. $b' < b \Rightarrow a' \mapsto f(a', b')$ is an increasing function
4. $b' > b \Rightarrow a' \mapsto f(a', b')$ is a decreasing function

We prove 1 (the rest are left as an exercise). Let $b'_1, b'_2 <_s b$ and $b'_1 < b'_2$. Then

$$\begin{aligned} f(a', b'_2) > f(a', b'_1) &\Leftrightarrow (a'b + ab'_2 - a'b'_2) > (a'b + ab'_1 - a'b'_1) \\ &\Leftrightarrow (ab'_2 - a'b'_2) > (ab'_1 - a'b'_1) \\ &\Leftrightarrow P(a, a', b'_2, b'_1) \end{aligned}$$

and $P(a, a', b'_2, b'_1)$ holds by induction, proving 1.

1-4 in the claim give us respectively:

1. $f(a_L, b_L) < f(a_L, b_R)$
2. $f(a_R, b_R) < f(a_R, b_L)$
3. $f(a_L, b_L) < f(a_R, b_R)$
4. $f(a_R, b_R) < f(a_L, b_L)$

These facts exactly give us that $a \cdot b$ is well-defined.

We are left to show that (*) continues to hold. We'll continue this on Wednesday. □

Wednesday 10-15-2014

Recall the definition of multiplication from last time:

$$a \cdot b = \{a_L \cdot b + a \cdot b_L - a_L \cdot b_L, a_R \cdot b + a \cdot b_R - a_R \cdot b_R | a_L \cdot b + a \cdot b_R - a_L \cdot b_R, a_R \cdot b + a \cdot b_L - a_R \cdot b_L\}$$

and the statement $(*) : a > b, c > d \Rightarrow ac - bc > ad - bd$. We'll also continue write $P(a, b, c, d) \Leftrightarrow ac - bc > ad - bd$.

Note we can rephrase the defining inequalities for $a \cdot b$ as

$$(\Delta) : P(a, a_L, b, b_L), P(a_R, a, b_R, b), P(a, a_L, b_R, b), P(a_R, a, b, b_L)$$

To finish the proof of Lemma 2.9, suppose $a > b > c > d$ (of suitable lengths). We want to show $P(a, b, c, d)$.

Case 1: Suppose in each pair $\{a, b\}, \{c, d\}$ one of the elements is an initial segment of the other. Then note we are done by (Δ) .

Case 2: Suppose $a \not<_s b, b \not<_s a$ but $c <_s d$ or $d <_s c$. Then we have that $a > a \wedge b > b$ and by Case 1, $P(a, a \wedge b, c, d)$ and $P(a \wedge b, b, c, d)$. This implies (by transitivity of the first two variables) $P(a, b, c, d)$.

Case 3: Suppose $c \not<_s d, d \not<_s c$. Then by Case 1 and 2, $P(a, b, c, c \wedge d)$ and $P(a, b, c \wedge d, d)$, so (transitivity of the last two variables) $P(a, b, c, d)$ as needed. This completes the proof of 2.9. □

Lemma 2.10. *The uniformity property holds for multiplication.*

Proof. Fix $a, b \in \mathbf{No}$. For any $a', b' \in \mathbf{No}$ we define (as last time) $f(a', b') = a'b + ab' - a'b'$. Using Lemma 2.9, we can extend the Claim from last time to hold in general:

Claim:

1. $a' < a \Rightarrow f(a', -)$ is an increasing function
2. $a' > a \Rightarrow f(a', -)$ is a decreasing function
3. $b' < b \Rightarrow f(-, b')$ is an increasing function
4. $b' > b \Rightarrow f(-, b')$ is a decreasing function

Let $a = \{L|R\}, b = \{L'|R'\}$ be any representations of a, b . We want to verify the hypothesis of the Cofinality Theorem 1.9.

Let a_l, b_l range over L, L' . As an example, note

$$f(a_l, b_l) < ab \Leftrightarrow 0 < ab - (a_l b + ab_l - a_l b_l) = (ab - a_l b) - (ab_l - a_l b_l) \Leftrightarrow P(a, a_l, b, b_l)$$

which holds as $a_l < a, b_l < b$. Checking the other inequalities in a similar manner gives us the first assumption of Theorem 1.9.

To get the second assumption (the cofinality hypothesis), let e.g. $f(a_L, b_L)$ in the left side of the representation of ab . By inverse cofinality, we get $a_l \in L, b_l \in L'$ with $a_l \geq a_L, b_l \geq b_L$. Then (using (3) and (1) respectively from the above claim): $f(a_l, b_l) \geq f(a_L, b_l) \geq f(a_L, b_L)$ as needed. Again, the other cases are similar. \square

Therefore, both assumptions of Theorem 1.9 hold, giving us the uniformity property for multiplication as needed.

Proposition 2.11.

$(\mathbf{No}, +, \cdot, \leq)$ is an ordered commutative ring, with multiplicative identity $1 = (+) = \{0|\emptyset\}$.

Proof. Commutativity is clear by the symmetry in the definition.

We show the distributive law by induction on $l(a) \oplus l(b) \oplus l(c)$ that $(a + b) \cdot c = a \cdot c + b \cdot c$.

In general, the typical element in the cut for $(a + b) \cdot c$ is $(a + b)_* c + (a + b)_* c_* - (a + b)_* c_*$ (where $(a + b)_*$ is either $(a + b)_L$ or $(a + b)_R$ and similar for c_*). This element is less than $(a + b)c$ if and only if there are 0 or 4 $*$'s equal to R .

By uniformity, we can replace $(a + b)_*$ with $a_* + b, a + b_*$, so the typical terms become (using induction):

$$(a_* + b)c + (a + b)c_* - (a_* + b)c_* = a_* c + bc + ac_* - a_* c_*$$

or similarly

$$(a + b_*)c + (a + b)c_* - (a + b_*)c_* = ac + b_* c + bc_* - b_* c_*$$

On the other hand, the typical elements of $ac + bc$ are

$$(ac)_* + bc = a_* c + ac_* - a_* c_* + bc \text{ or } ac + (bc)_* = ac + b_* c + bc_* - b_* c_*$$

(note the same parity rule for $*$'s applies here.) A quick check shows that this matches a typical element of $(a + b) \cdot c$ we have $(a + b)c = ac + bc$ as needed.

Associativity is proven using a very similar argument (and is left as an exercise).

We are left to check the identity element. Note $a \cdot 0 = a \cdot (0 + 0) = a \cdot 0 + a \cdot 0$ which implies $a \cdot 0 = 0$.

By definition:

$$a \cdot 1 = \{a_L \cdot 1 + a \cdot 1_L - a_L \cdot 1_L, a_R \cdot 1 + a \cdot 1_R - a_R \cdot 1_R | a_L \cdot 1 + a \cdot 1_R - a_L \cdot 1_R, a_R \cdot 1 + a \cdot 1_L - a_R \cdot 1_L\}$$

Using the fact that $1_R = \emptyset$ and multiplication by $0 = 1_L$ is zero, we have

$$a \cdot 1 = \{a_L \cdot 1 | a_R \cdot 1\} = \{a_L | a_R\} = a$$

by induction. This completes the proof. \square

Our next goal is to define $1/a$ for $a > 0$, i.e. find a solution to $a \cdot x = 1$. Note, the naive idea is to set $x = \{1/a_R | 1/a_L, (a_L \neq 0)\}$ but this does not work in general.

Friday 10-17-2014

Definition 2.12. Let $a \in \mathbf{No}$ with $a > 0$. Our aim is to define $1/a$. Let $a = \{L | R\}$ the canonical representation of a . Observe that $a' \geq 0$ for all $a' \in L$ (as $a' <_s a$).

For every finite sequence $(a_1, \dots, a_n) \in (L \cup R) \setminus \{0\}$ we define $\langle a_1, \dots, a_n \rangle \in \mathbf{No}$ by induction on n . Set $\langle \rangle = 0$ and inductively set $\langle a_1, \dots, a_n, a_{n+1} \rangle = \langle a_1, \dots, a_n \rangle \circ a_{n+1}$. Here, for arbitrary $b \in \mathbf{No}$ and $a' \in (L \cup R) \setminus \{0\}$ let $b \circ a'$ be the unique solution to $(a - a')b + a'x = 1$, i.e.

$$b \circ a' = [1 - (a - a')b] / a'.$$

This works as inductively we'll have already defined $1/a'$.

For example, $\langle a_1 \rangle = \langle \rangle \circ a_1 = 0 \circ a_1 = 1/a_1$.

Now set (as candidates for defining $1/a$)

$$\begin{aligned} L^{-1} &= \{\langle a_1, \dots, a_n \rangle \mid \text{the number of } a_i \text{ in } L \text{ is even}\} \\ R^{-1} &= \{\langle a_1, \dots, a_n \rangle \mid \text{the number of } a_i \text{ in } L \text{ is odd}\} \end{aligned}$$

Note that this definition is an expansion of the naive idea presented at the end of last lecture.

We first show

$$(*) x \in L^{-1} \Rightarrow ax < 1 \text{ and } x \in R^{-1} \Rightarrow ax > 1.$$

by induction on n . In particular, this yields that $L^{-1} < R^{-1}$.

The base case is clear, as $\langle \rangle = 0 \in L^{-1}$ and $a \cdot 0 = 0 < 1$.

For the induction, suppose $b \in L^{-1} \cup R^{-1}$ satisfying $(*)$ and $0 \neq a' <_s a$. We show that $x = b \circ a'$ also satisfies $(*)$.

Claim:

1. $x > b \Leftrightarrow 1 > ab$
2. $ax = 1 + (a - a')(x - b)$.

By definition, x is the solution to $(a - a')b + a'x = 1$ and $ab = ab - a'b + a'b = (a - a')b + a'b$. These two equations yield $ab = 1 + a'(b - x)$. Both parts of the claim follow.

Now suppose, $b \in L^{-1}, a' \in L$. Then $x \in R^{-1}$ so want to check $ax > 1$. $b \in L^{-1}$ and $(*)$ implies that $ab < 1$ and hence Claim 1 tells us that $x > b$. Now by Claim 2, $ax = 1 + (a - a')(x - b)$ hence $ax > 1$ (because $a > a', x > b$) as needed.

The other cases are similar, so $(*)$ holds in general.

Thus, we can set $c = \{L^{-1} | R^{-1}\}$. We claim that $1/a = c$, that is, $ac = 1 = \{0 | \emptyset\}$.

The typical element used to define ac is $a'c + ac' - a'c'$ with $a' \in L \cup R, c' \in L^{-1} \cup R^{-1}$.

We first show $\{\text{lower elements for } ac\} < 1 < \{\text{upper elements for } ac\}$.

Suppose that $a' = 0$, then we get an element $a'c + ac' - a'c' = ac'$ which is an upper element for ac if and only if $c' \in R^{-1}$ by definition. However, by $(*)$ if $c' \in R^{-1}$ then $ac' = a'c + ac' - a'c' > 1$ (as needed since an upper element), else $c' \in L^{-1}$ and then $ac' = a'c + ac' - a'c' < 1$ (as needed since a lower element).

If $a' \neq 0$, then $x = c' \circ a'$ is defined, lies in $L^{-1} \cup R^{-1}$, and obeys $(\Delta) : (a - a')c' + a'x = 1$. Hence,

$$\begin{aligned} a'c + ac' - a'c' \text{ is a lower element for } ac &\Leftrightarrow a' \text{ \& } c' \text{ are on the same side of } a \text{ \& (respectively) } c \\ &\Leftrightarrow x \in R^{-1} \Leftrightarrow x > c \\ &\Leftrightarrow \text{a typical element } a'c + ac' - a'c' = (a - a')c' + a'c < 1 \end{aligned}$$

where the last equivalence holds by (Δ) and $a' > 0$.

Since 1 satisfies the cut for ac (and 0 does not) it is the minimal realization, so $ac = 1$ as needed.

We have thus shown:

Theorem 2.13. *(No, +, ·, ≤) is an ordered field.*

October 20th

3 Real Numbers

We'll now begin to focus on how to view real numbers and ordinals as surreal numbers.

We have $0 = ()$ the additive identity of **No** and $1 = (+)$ the multiplicative identity of **No**.

We also have an embedding of ordered rings $\mathbb{Z} \hookrightarrow \mathbf{No}$ where $k \mapsto k \cdot 1$ (where $k \cdot 1$ is k additions of $+1$ or -1).

Lemma 3.1. For $n \in \mathbb{N}$, $n \cdot 1 = \underbrace{(+ + \cdots +)}_{n \text{ times}}$.

Proof. By induction on n . The cases $n = 0, 1$ are obvious. Suppose that $n \geq 1$. We have

$$\begin{aligned}
 (n+1) \cdot 1 &= n \cdot 1 + 1 \\
 &= (+ + \cdots +) + (+) \\
 &= \{ \underbrace{(+ \cdots +)}_{n-1} \mid \emptyset \} + \{ 0 \mid \emptyset \} \\
 &= \{ (n-1) \cdot 1 \mid \emptyset \} + \{ 0 \mid \emptyset \} \\
 &= \{ (n-1) \cdot 1 + 1, n \cdot 1 + 0 \mid \emptyset \} \\
 &= \{ n \cdot 1 \mid \emptyset \} \\
 &= \{ \underbrace{(+ + \cdots +)}_n \mid \emptyset \} \\
 &= \underbrace{(+ + \cdots +)}_{n+1}.
 \end{aligned}$$

□

Corollary 3.2. For $n \in \mathbb{N}$, $-n \cdot 1 = \underbrace{(- - \cdots -)}_{n \text{ times}}$.

An ordered field k is *archimedean* if for all $a, b > 0$ in k there is $n \in \mathbb{N}$ such that $na > b$.

Note: **No** is not archimedean, since $\omega := (+ + \cdots)$ (with ω many $+$ s) satisfies $\omega > \underbrace{(+ \cdots +)}_n = n \cdot 1$.

From now on we identify \mathbb{Z} as a subring of **No**.

Q: How to identify $\mathbb{Q} \subseteq \mathbf{No}$?

Idea: $0 = () < (+-) < (+) = 1$. Is $(+ -) = \frac{1}{2}$?

Finite sequences of $+$ s and $-$ s correspond to dyadic rationals, i.e., rationals of the form $\frac{a}{2^s}$ ($a \in \mathbb{Z}$, $s \in \mathbb{N}$).

We might conjecture that \mathbb{Q} corresponds to finite sequences in **No**.

Lemma 3.3. Suppose $a + b = \{2a \mid 2b\}$. Then $\frac{a+b}{2} = \{a \mid b\}$.

Proof. Put $c := \{a \mid b\}$. Then $2 \cdot c = c + c = \{a + c \mid b + c\}$, and we show that this equals $a + b$:

$$a + c < a + b < b + c, \text{ since } a < c < b, \text{ and}$$

$$2a < a + c, \quad 2b > b + c \text{ because } a < c < b.$$

Now the result follows by the uniformity of the definition of $+$: since we assumed $a + b = \{2a \mid 2b\}$, we get the claim by cofinality. □

Example 3.4. $1 = \{0 \mid \emptyset\} = \{0 \mid 2\}$. Apply the lemma with $a = 0$, $b = 1$. So $\frac{1}{2} = \{0 \mid 1\} = (+-)$. Taking $a = 0$, $b = \frac{1}{2}$, we get $\frac{1}{4} = (+--)$.

Corollary 3.5. Suppose $a + b = \{2a \mid 2b\}$. Then

$$\frac{a+b}{2^{s+1}} = \left\{ \frac{a}{2^s} \mid \frac{b}{2^s} \right\}$$

for all $s \in \mathbb{N}$.

Corollary 3.6. For all $c \in \mathbb{N}$, $\frac{c}{2^s} + \frac{1}{2^{s+1}} = \left\{ \frac{c}{2^s} \mid \frac{c+1}{2^s} \right\}$.

Proof. Take $a = c$, $b = c + 1$. We have

$$\begin{aligned} a + b &= 2c + 1 \\ &= \{2c \mid 2c + 2\} \\ &= \{2a \mid 2b\}. \end{aligned}$$

Apply Corollary 3.5. □

Proposition 3.7. Surreal numbers of finite length correspond to dyadic rationals.

Proof. Let $d \in \mathbf{No}$ have length $m+n$, where $d(0) = d(1) = \dots = d(m-1) \neq d(m)$. We'll show that $d \in \frac{1}{2^n}\mathbb{Z}$. Suppose $d(0) = d(m-1) = +$. (Similar if $d(0) = -$)

$n = 0$: follows by (3.1).

$n = 1$: Then $d = (\underbrace{++ \dots +}_{m \geq 1} -)$. By (3.6) with $c = m-1$, $s = 0$, $m - \frac{1}{2} = \frac{m-1}{2^0} + \frac{1}{2^1} = \{m-1 \mid m\}$. Clearly $\{m-1 \mid m\} = d$.

Now suppose we've shown the claim for all $n \geq r$, and let $n = r+1$; suppose $r \geq 1$. Let $d' = d \upharpoonright (m+r)$. Either $d = d' \frown (+)$ or $d = d' \frown (-)$; suppose wlog that $d = d' \frown (+)$. So $d' = (\underbrace{++ \dots +}_m - \dots)$. Let

$d = \{L \mid R\}$ be the canonical representation. Taking $x = \max L$, $y = \min R$, we have $d = \{x \mid y\}$ by cofinality. Note $x = d'$. We don't know much about y except that

$$d = (\underbrace{++ \dots +}_m - \dots -) \leq (\underbrace{++ \dots +}_m) = m,$$

so $y \leq m$. By inductive hypothesis, $x, y \in \frac{1}{2^r}\mathbb{Z}$. So $d' = x = \frac{c}{2^r}$ for some $c \in \mathbb{N}$. If we can show $y = \frac{c+1}{2^r}$, then by (3.6)

$$d = \{x \mid y\} = \frac{c}{2^r} + \frac{1}{2^{r+1}} \in \frac{1}{2^{r+1}}\mathbb{Z},$$

as required.

Note

$$m-1 < x = d' = \frac{c}{2^r} < \frac{c+1}{2^r} \leq y \leq m.$$

Put $H := \{h \in \mathbf{No} : \ell(h) \leq m+r \text{ \& } h \upharpoonright (m+1) = (++ \dots + -)\}$. We have $|H| = 1+2+2^2+\dots+2^{r-1} = 2^r-1$. By inductive hypothesis every $h \in H$ belongs to $\frac{1}{2^r}\mathbb{N}$, and $m-1 < h < m$. But there are exactly 2^r-1 many dyadic rationals satisfying both of these conditions. In particular, $\frac{c+1}{2^r} \in H$ or $\frac{c+1}{2^r} = m$. Either way, $\ell(\frac{c+1}{2^r}) \leq m+r$. Since $\frac{c+1}{2^r} > d'$, this implies $\frac{c+1}{2^r} > d$. We have $\frac{c+1}{2^r} <_s d$: otherwise $e := \frac{c+1}{2^r} \wedge d$ will satisfy $d < e < \frac{c+1}{2^r} \leq y$, contradiction to choice of y . Hence $\frac{c+1}{2^r} \in R$, so $\frac{c+1}{2^r} \geq y$. □

October 22nd

Remark (to (3.7)). Suppose $d \in \mathbf{No}$ has length $m + n$, where

- $d(0) = \dots = d(m-1)$, and
- $d(m-1) \neq d(m)$.

Define

$$b(i) := \begin{cases} \pm 1 & \text{if } i < m, \quad d(i) = \pm \\ \pm \frac{1}{2^{i-m+1}} & \text{if } i \geq m, \quad d(i) = \pm. \end{cases}$$

Then $d = b(0) + b(1) + \dots + b(m+n-1)$. (Exercise.) Also, every dyadic rational arises in this way. (Exercise.) We now let \mathbb{D} be the set of dyadic rationals $\mathbb{Z}[\frac{1}{2}] \subseteq \mathbb{Q}$.

Definition 3.8. A surreal is called *real* if it is either of finite length or has length ω and is not ultimately constant.

Recall: An ordered field k is *dedekind-complete* if every nonempty subset of k that is bounded from above has a supremum. The ordered field \mathbb{R} is up to (unique) isomorphism the only dedekind-complete ordered field.

Theorem 3.9 (Conway). *The real surreals form a dedekind-complete ordered subfield of \mathbf{No} . Let $a \in \mathbf{No}$, $\ell(a) = \omega$, with canonical representation $a = \{L \mid R\}$ then*

$$a \text{ is real} \iff \begin{cases} L, R \neq \emptyset \\ L \text{ has no max} \\ R \text{ has no min} \end{cases}.$$

The direction “ \Rightarrow ” is an exercise. Now we prove the other direction.

Lemma 3.10. *Let $L, R \subseteq \mathbb{D}$ be such that $L < R$ and L has no max and R has no min. Then $a = \{L \mid R\}$ is real.*

Proof. By (1.7) we have $\ell(a) \leq \omega$. Suppose $\ell(a) = \omega$ and $a(n) = +$ eventually. Note that there is some n_0 with $a(n_0) = -$, since $a < R \neq \emptyset$. We may assume that $a(n) = +$ for all $n > n_0$. Let $b = a \upharpoonright n_0$. Then $b > a$ and $b <_s a$. Since (L, R) is cofinal in the canonical representation of a , there is $d \leq b$, $d \in R$. It follows that $d \in R$, since R has no least element. We can choose m such that $d \leq b - \frac{1}{2^m}$. (Possible since both b & d are dyadics.) We get $a < d \leq b - \frac{1}{2^m}$. Next let $n > n_0$, $c = a \upharpoonright n$. Then $c < a$ and $c <_s a$, so by choosing n sufficiently large we can achieve $c > b - \frac{1}{2^m}$. But then $a > c > b - \frac{1}{2^m}$, oops.

(Why can we do this? Write

$$c = k + \sum_{i=l}^{n-1} \pm \frac{1}{2^{i-l+1}}$$

and

$$b = k + \sum_{i=l}^{n_0-1} \pm \frac{1}{2^{i-l+1}}.$$

Then we get

$$c - b = -\frac{1}{2^{n_0-l+1}} + \frac{1}{2^{n_0-l+2}} + \dots + \frac{1}{2^{n-l}} = -\frac{1}{2^{n_0-l+1}} + \left(\frac{1}{2^{n_0-l+1}} - \frac{1}{2^{n-l}} \right) = \frac{-1}{2^{n-l}},$$

so just choose $n > l + m$. □

Lemma 3.11. *Let $a = \{L \mid R\}$. Suppose*

1. $x \in L \Rightarrow \exists r \in \mathbb{D}^{>0}, y \in L, x + r \leq y$. [$“L - \mathbb{D}^{>0}$ is cofinal in $L”$]

2. $x \in R \Rightarrow \exists r \in \mathbb{D}^{>0}, y \in R, y \leq x - r$. [$R + \mathbb{D}^{>0}$ is coinitial in R .]
 and also $L' < a < R'$ such that
 3. $(\forall r \in \mathbb{D}^{>0})(\exists x' \in L')(\exists y' \in R')y' - x' \leq r$. [$R' - L'$ is coinitial in $\mathbb{D}^{>0}$]

Then $a = \{L' \mid R'\}$.

Proof. Check that (L', R') is cofinal in (L, R) and use the cofinality theorem. \square

Lemma 3.12. \mathbb{D} is dense in the ordered set of real surreals.

Proof. Let $a < b$ be reals. If neither $a <_s b$ nor $b <_s a$ then $a < a \wedge b < b$. (Note $a \wedge b$ is finite, so it's in \mathbb{D} .) So suppose that $a <_s b$. Then $a \in \mathbb{D}$. If also $b \in \mathbb{D}$, then we're done: $a < \frac{a+b}{2} < b$. So suppose $b \notin \mathbb{D}$, with canonical representation $b = \{L \mid R\}$. Then $a \in L$, and L has no maximum, so we can find some dyadic element of (a, b) . Similar if $b <_s a$. \square

Lemma 3.13. Let $a = \{L \mid R\}$ be the canonical representation of a real $a \notin \mathbb{D}$. Then for all $r \in \mathbb{D}^{>0}$ there are a_L, a_R with $a_R - a_L \leq r$.

Proof. For each n there are a_L, a_R with $a_L \upharpoonright n = a_R \upharpoonright n$, and $a_R - a_L$ is bounded from above by some expression $\frac{1}{2^s} + \frac{1}{2^{s+1}} + \dots$, and this can be made as small as necessary. (Exercise.) \square

October 24th

Proof of Theorem 3.9. Clearly $0, 1$ are real. Let $a, b \in \mathbf{No}$ be real; we check that $a + b, a \cdot b, \frac{1}{a}$ (if $a \neq 0$) are also real. (Note that $-a$ is obviously real.)

$a + b$

Suppose $a \in \mathbb{D}, b \notin \mathbb{D}$. Let $a = \{L \mid R\}$ be the canonical representation. So $a + b = \{a_L + b, a + b_L \mid a_R + b, a + b_R\}$. We claim that $a + b = \{a + b_L \mid a + b_R\}$. (By (3.10) this then gives $a + b$ real, since b_L, b_R dyadic.) We have $a, a_L \in \mathbb{D}$, so $a - a_L \in \mathbb{D}^{>0}$; hence by (3.13) there are b_L, b_R such that $b_R - b_L \leq a - a_L$. It follows that $a + b_L \geq a_L + b_R \geq a_L + b$. Now use cofinality. (Similar argument for the other side.)

Now suppose that $a, b \notin \mathbb{D}$. Then in the representation of $a + b$ the LHS has no max and the RHS has no min. So (1) & (2) in (3.11) are satisfied for this cut. Let $L' := \{a_L + b_L\}, R' := \{a_R + b_R\}$. Then $L' < a + b < R'$ and by (3.13) (L', R') satisfies (3) in (3.11). This means that $a + b = \{L' \mid R'\}$ by (3.11), and this is real by (3.10).

$a \cdot b$

Suppose $a \notin \mathbb{D}, a, b > 0$. The typical element in the representation of $a \cdot b$ is $ab - (a - a_*)(b - b_*)$. Show that (1), (2) in (3.11) are satisfied by this cut. For example,

$$x = ab - (a - a_L)(b - b_L).$$

Take a'_L with $a_L < a'_L < a$ and set $x' = ab - (a - a'_L)(b - b_L)$. Then by (3.12) $x' - x = (a'_L - a_L)(b - b_L)$ is greater than some element of $\mathbb{D}^{>0}$. This verifies (1) of (3.11). In the same way verify (2). Now set

$$\begin{aligned} L' &:= \{a'b' : a', b' \in \mathbb{D}, 0 \leq a' < a, 0 \leq b' < b\}, \\ R' &:= \{a''b'' : a'', b'' \in \mathbb{D}, a'' > a, b'' > b\}. \end{aligned}$$

Then $L' < a \cdot b < R'$. We check that (3.11)(3) holds. Let $r \in \mathbb{D}^{>0}$ be given. Then the same argument as proving the limit law for multiplication in calculus gives elements a', b', a'', b'' such that $a''b'' - a'b' < r$, using (3.13). Hence by (3.11) $a \cdot b = \{L' \mid R'\}$, so ab is real by (3.10).

$1/a$:

We may assume that $a > 0$. Put

$$\begin{aligned} L &:= \{d \in \mathbb{D} : d \frown a < 1\} \\ R &:= \{d \in \mathbb{D} : d \frown a > 1\}. \end{aligned}$$

Then $L < R$, $0 \in L$, and $R \neq \emptyset$ because: by (3.12) take m such that $a > \frac{1}{2^m}$, so that $2^m a > 1$. So $2^m \in R$.

Claim 1. L has no max; R has no min.

Proof of Claim 1. Let $d \in L$. Then $1 - da > 0$ is real. So there is some m such that $1 - da > \frac{1}{2^m}$. Also can take n such that $a < 2^n$. Then $\frac{1}{2^{m+n}}a < \frac{1}{2^m} < 1 - da$, so $a(\frac{1}{2^{m+n}} + d) < 1$. \square

Hence by (3.10) $b := \{L \mid R\}$ is real. We are going to show that $|ba - 1| < r$ for every $r \in \mathbb{D}^{>0}$. Since $ba - 1$ is real, we get $ba - 1 = 0$ by (3.12).

Claim 2. For each n there is $c \in R$ such that $ca \leq 1 + \frac{1}{2^n}$, and there is $c' \in L$ such that $c'a \geq 1 - \frac{1}{2^n}$.

(Obviously this suffices.)

Proof of Claim 2. Choose m such that $2^m > a$. Put $S := \{r \in \mathbb{N} : (\frac{r}{2^{m+n}})a > 1\}$. Then $S \neq \emptyset$; take $s = \min S$. Then $\frac{s}{2^{m+n}} \in R$, but $(\frac{s-1}{2^{m+n}})a \leq 1$. So

$$\frac{s}{2^{m+n}}a \leq 1 + \frac{a}{2^m 2^n} \leq 1 + \frac{1}{2^n}. \quad \square$$

This completes the proof. \square

Week 4

Notes by Madeline Barnicle

Monday, October 27, 2014

We need to show that the ordered field of reals in **No** is Dedekind-complete.

Let $S \neq \emptyset$ be a set of reals which is bounded from above. We need to show $\sup S$ exists. We can assume S has no maximum. Put $R = \{a \in \mathbb{D} : a > S\}$, $L = \mathbb{D} \setminus R$. Using (3.11), the density of \mathbb{D} , L has no maximum. If R has a minimum, then this value is the sup of S and we are done. So suppose R has a minimum, then $r = \{L|R\}$ is real.

Claim: $r = \sup S$. Suppose $s \in S$ satisfies $s > r$, take $d \in \mathbb{D}$ with $s > d > r$. Then $d \in L$, contradiction since $d > r$.

So r is an upper bound. If $L < r' < r$, r' also real, take dyadic d with $r' < d < r$. Then $d \in R$, contradiction.

Corollary 3.14. Corollary to (3.8) and (3.12): Let $a \in \mathbb{R} \setminus \mathbb{D}$. Then $\lim_{n \rightarrow +\infty} a \upharpoonright n = a$ in \mathbb{R} .

====Ordinals==== We identify each $n \in \mathbf{On}$ with $a_\alpha \in \mathbf{No}$, where $l(a_\alpha) = \alpha$ and $a_\alpha(\beta) = +$ (for all $\beta \leq \alpha$?) For all $\alpha, \beta \in \mathbf{On}$, $\alpha \leq \beta \rightarrow a_\alpha < a_\beta$.

The canonical representation of a_α is $a_\alpha = \{a_\beta, \beta \leq \alpha | \emptyset\}$.

If H is any nonempty set of ordinals and $\alpha = \sup H$, then $a_\alpha = \{a_\beta, \beta \in H | \emptyset\}$.

Proposition 3.15. For all $\alpha, \beta \in \mathbf{On}$, $a_\alpha + a_\beta = a_{\alpha \oplus \beta}$, $a_\alpha * a_\beta = a_{\alpha \otimes \beta}$.

Proof. By induction, $a_\alpha + a_\beta = \sup \{a_\alpha + a_{\beta'}, a_{\alpha'} + a_\beta | \alpha' \leq \alpha, \beta' \leq \beta\} =$ by induction, $\sup \{a_{\alpha' \oplus \beta}, a_{\alpha \oplus \beta'} | \alpha' \leq \alpha, \beta' \leq \beta\} = a_{\alpha \oplus \beta}$, stated earlier.

For multiplication, using the result for addition, and the distributive laws for $+$, \cdot , on **No** and \oplus, \otimes on **On**, we reduce to the case $\alpha = \omega^r, \beta = \omega^s, r, s \in \mathbf{On}$. By definition, $a_\alpha * a_\beta = \{a_{\omega^r} * a_\delta + a_\gamma * a_{\omega^s} - a_\delta * a_\gamma : \delta \leq \omega^s, \gamma \leq \omega^r | \emptyset\}$. In particular, $a_\alpha * a_\beta \in \mathbf{On}$ by (1.8). By inductive hypothesis and the first part, $a_{\omega^r} * a_\delta + a_\gamma * a_{\omega^s} - a_\delta * a_\gamma \leq a_{(\omega^r \otimes \delta) \oplus (\delta \otimes \omega^s)} < a_{\omega^{r \oplus s}}$.

And $l(a_\alpha * a_\beta) \leq l(\omega^{r \oplus s}) = \omega^{r \oplus s}$.

Now we show the \geq direction.

Let $r' < r$ and $n \in \mathbb{N}$, then $a_\alpha * a_\beta > a_{\omega_n^{r'}} * a_\beta = a_{\omega_n^{r'}} \otimes \beta$ by hypothesis $= a_{\omega_n^{r'} \oplus s}$. Similarly if $s' < s, n \in \mathbb{N}$, then $a_\alpha * a_\beta > a_{\omega_n^{r \oplus s'}}$. Therefore, $a_\alpha * a_\beta \geq \sup \{a_{\omega_n^{r' \oplus s}}, a_{\omega_n^{r \oplus s'}} : r' < r, s' < s, n \in \mathbb{N}\} = a_{\omega^{r \oplus s}}$. (See the definition of natural \oplus .) \square

====Examples====

1. $\omega - 1 = \omega + (-1) = \{n | \emptyset\} + \{\emptyset | 0\} = \{n - 1 | \omega + 0\} = \{n | \omega\} = (++++\dots)(\omega + s)$.
2. $\omega - (m + 1)$? By hypothesis, assume $\omega - m = (++++\dots - - - \dots)(\omega + s \text{ and } m - s)$. $\omega - (m + 1) = \{n | \emptyset\} + \{\emptyset | -m\} = \{n - m - 1 | \omega - m\} = \{n | \omega - m\} = (++++\dots - - - \dots)(\omega + s \text{ and } m + 1 - s)$.
3. $\omega + \frac{1}{2} = \{n | \emptyset\} + \{0 | 1\} = \{n + \frac{1}{2} | \omega + 0 | \omega + 1\} = \{\omega | \omega + 1\} = (++++\dots + -)(\omega + s)$.
4. In general, if $r \in \mathbb{R}^{>0}$, $\omega + r = \{n | \emptyset\} + \{L | R\}$ (the canonical representation for r) $= \omega + L, n + r | \omega + R = \{\omega + L | \omega + R\}$. Inducting on the length of r , this equals $\omega \frown r$. This also works for negative, non-integer r (we need L to be nonempty for the argument to go through)—the full result holds for $r \in \mathbb{Z}^{<0}$ as well.

Wednesday, October 29, 2014

1. $\frac{1}{2}\omega = \{0 | 1\} * \{n | \emptyset\} =$ by the definition of multiplication, $\{\frac{1}{2}n + \omega * 0 - n * 0 | \frac{1}{2}n + \omega * 1 - n * 1\} = \{\frac{1}{2}n | \omega - \frac{1}{2}n\} =$ by cofinality $\{n | \omega - n\} = (++++\dots - - - \dots)(\omega + s, \omega - s)$.

2. $\frac{1}{\omega} = (+ - - - \dots)$ (ω -s)? Call this number ϵ . $0 < \epsilon < r$ for all $r \in \mathbb{R}^{>0}$, i.e. ϵ is "infinitesimal". (It is the unique infinitesimal of length ω .) Guess that $\epsilon = \frac{1}{\omega}$. Canonical representation of $\epsilon : \{0 | \frac{1}{2^n}\}$.

$$\epsilon\omega = \{0 | \frac{1}{2^n}\} * \{m | \emptyset\} = \{0 | \frac{1}{n}\} * \{m | \emptyset\} \text{ by cofinality} = \{\epsilon * m + 0 * 0 - 0 * \omega | \epsilon * m + \frac{1}{n}\omega - \frac{1}{n}m\} = \{\epsilon * m | \epsilon * m + \frac{1}{n}\omega - \frac{1}{n}m\}.$$

Now $\epsilon * m$ is still infinitesimal, $\epsilon m < 1.1 < \epsilon * m + \frac{1}{n}\omega - \frac{1}{n}m$, as $\frac{1}{n}(\omega - n)$ is infinite. Since 0 does not satisfy the cut, $\epsilon\omega = 1$.

1. $r + \epsilon (r \in \mathbb{R})$. First assume $r \in \mathbb{D}$, so $r = \{r_L | r_R\}$, $r_L, r_R \in \mathbb{D}$. $r + \epsilon = \{r_L + r_R\} + \{0 | \frac{1}{n}\} = \{r + 0, r_L + \epsilon | r + \frac{1}{n}, r_R + \epsilon\} = \{r | r + \frac{1}{n}\}$ by cofinality $= \{r | \mathbb{D}^{>r}\} = r \frown (+)$, of length $\omega + 1$.
2. What is $\lambda + r$, λ a limit ordinal, $r \in \mathbb{R}$?

4 Combinatorics of Ordered Sets

Let S be a set. An **ordering** \leq on S is an reflexive, transitive, antisymmetric, binary relation on S . Call (S, \leq) an **ordered set** (partial or total).

We say \leq is **total** if $x \leq y$ or $y \leq x$ for each $x, y \in S$.

Let T be an ordered set, and $\phi : S \rightarrow T$ a map. Then ϕ is **increasing** if $x \leq y \rightarrow \phi(x) \leq \phi(y)$, **strictly increasing** if $x < y \rightarrow \phi(x) < \phi(y)$, a **quasi-embedding** if $\phi(x) \leq \phi(y) \rightarrow x \leq y$.

Examples: let $(S, \leq_S), (T, \leq_T)$ be ordered sets.

1. $S \amalg T =$ disjoint union of S and T with the ordering $\leq_S \cup \leq_T$.
2. $S \times T$ can be equipped with the "product ordering" $(x, y) \leq (x', y') \leftrightarrow x \leq_S x' \text{ and } y \leq_T y'$, or the "lexicographic ordering" $(x, y) \leq_{lex} (x', y') \leftrightarrow x <_S x' \text{ or } (x = x' \text{ and } y \leq_T y')$. The lexicographic ordering extends the product ordering.
3. Let S^* be the set of finite words on S . Define $x_1 \dots x_m \leq^* y_1 \dots y_n$ if there exists a strictly increasing $\phi : \{1 \dots m\} \rightarrow \{1 \dots n\}$ such that $x_i \leq_S y_{\phi(i)}$ for every $i = 1 \dots m$.
4. Let S° be the set of "commutative" finite words on $S = S^* / \sim$, where $x_1 \dots x_m \sim y_1 \dots y_n$ if $m = n$ and there exists a permutation of $\{1 \dots m\}$ such that $x_i = y_{\phi(i)}$ for all i . Define $x_1 \dots x_m \leq^\circ y_1 \dots y_n \leftrightarrow$ there exists an injective $\phi : \{1 \dots m\} \rightarrow \{1 \dots n\}$ such that $x_i \leq_S y_{\phi(i)}$ for $i = 1 \dots m$.
5. The natural surjective map $(S^*, \leq^*) \rightarrow (S^\circ, \leq^\circ)$ is increasing.
6. $\mathbb{N}^m = \mathbb{N} * \mathbb{N} * \dots * \mathbb{N}$ with the product ordering. $X = \{x_1 \dots x_m\}$ distinct indeterminates with trivial ordering. The map $\mathbb{N}^m \rightarrow X^\circ, \nu(v_1 \dots v_n) = X_1^{v_1} \dots X_m^{v_m}$ is an isomorphism of ordered sets. \leq° is divisibility of monomials.

Let S be an ordered set. Call $F \subset S$ a "final segment" of S if $x \leq y$ and $x \in F \rightarrow y \in F$ (F is upward closed). Given $X \subset S$, define $(X) \subset F = \{y \in S | \exists x \in X, x \leq y\}$, the final segment of S "generated" by X (the notation corresponds to the ideal generated by monomials). Put $\mathcal{F}(S) =$ the set of all finite segments of S . Call $A \subset S$ an "antichain" if for $x, y \in A, x \neq y \rightarrow x \not\leq y$ and $y \not\leq x$. We say that S is "well-founded" if there is no infinite sequence $x_1 > x_2 \dots$ in S .

Definition 4.1. (S, \leq) is **noetherian** if it is well-founded and has no infinite antichains.

Friday, October 31, 2014

Call an infinite sequence (x_n) in S **good** if $x_i \leq x_j$ for some $i < j$.

Proposition 4.2. The following are equivalent:

1. S is Noetherian.

2. Every final segment of S is finitely generated.
3. $\mathcal{F}(S)$ has the ascending chain condition.
4. Every infinite sequence in S contains an increasing finite subsequence.
5. Every infinite sequence in S is good.

Proof. 1 \rightarrow 2: Let $F \in \mathcal{F}(S)$. Let G be the set of minimal elements of F . Then G is an antichain, hence finite. Suppose $x_i \in F \setminus (G)$, there is $x_2 \in F$ such that $x_1 > x_2, x_2 \ni (G)$. This yields an infinite sequence $x_1 > x_2 \dots$, a contradiction.

2 \leftrightarrow 3 is a standard argument.

3 \rightarrow 4: Let (x_i) be a sequence in S . We define a subsequence x_{n_k} such that $x_{n_k} \leq x_{n_{k+1}} \forall k$, and there are infinitely many $n > n_k$ such that $x_n > x_{n_k}$. We let $n_1 = 1$. Inductively, suppose we have already defined $n_1 \dots n_k$. Then the final segment $(x_n : n > n_k, x_n \geq x_{n_k})$ is finitely generated, so there is some $x_{n_{k+1}}$ such that for infinitely many $n > k$ with $x_n > x_{n_k}$ we have $x_n > x_{n_{k+1}}$.

4 \rightarrow 5 is obvious, as is 5 \rightarrow 1. \square

Corollary 4.3. 1. If there exists an increasing surjection $S \twoheadrightarrow T$ and S is noetherian, then T is noetherian. (Use condition 5.)

2. If there exists a quasi-embedding $S \rightarrow T$ and T is noetherian, then S is noetherian.
3. If S, T are noetherian, then so are $S \coprod T$ and $S \times T$. (For the product case, take an infinite sequence and apply condition 4 to each component.)

In particular, \mathbb{N}^m is noetherian (“Dickson’s Lemma”).

Theorem 4.4. If S is noetherian, then S^* is noetherian, (and then so is S^\diamond by (4.3 (1))).

Proof. (Nash-Williams)

Suppose $w_1, w_2 \dots$ is a bad sequence for \leq^* . We may assume that each w_n is of minimal length under the condition $w_n \ni (w_1 \dots w_{n-1})$. Then $w_n \neq \epsilon$ (the empty word) for any n . So $w_n = s_n * u_n, s_n \in S, u_n \in S^*$ (splitting off the first letter). Since S is noetherian, we can take an infinite subsequence $s_{n_1} \leq s_{n_2} \dots$ of s_n . By minimality, $w_1 \dots w_{n_1-1}, u_{n_1}, u_{n_2} \dots$ is good. So $\exists i < j$ such that $u_{n_i} \leq^* u_{n_j}$. Then $s_{n_i} u_{n_i} \leq s_{n_j} u_{n_j}$, that is, $w_{n_i} \leq w_{n_j}$, contradiction. \square

Remark: suppose $\phi : S \rightarrow T$ is a **strictly** increasing map of ordered sets, where S is noetherian. Then ϕ has finite fibers.

Application: Let $\Gamma = (\Gamma, \leq, +)$ be a totally ordered abelian group.

Corollary 4.5. Let A, B be subsets of Γ which are well-ordered. Then $A \cup B$ is well-ordered, and the set $A + B = \{\alpha + \beta \mid \alpha \in A, \beta \in B\}$ is well-ordered, and for every $\gamma \in A + B$, there are only finitely many $(\alpha, \beta) \in A \times B$ with $\gamma = \alpha + \beta$.

See (4.3) (3) and take increasing maps from $A \times B \rightarrow (A + B)$.

Corollary 4.6. Let $A \subset \Gamma^{>0}$ be well-ordered. Then $< A > = \{\alpha_1 + \dots \alpha_n : \alpha_i \in A\}$ is also well-ordered, and for each $\gamma \in < A >$ there are only finitely many $(n, \alpha_1 \dots \alpha_n)$ with $n \in \mathbb{N}, \alpha_1 \dots \alpha_n \in A$ such that $\gamma = \alpha_1 + \dots \alpha_n$.

Proof. We have the map $A^\diamond \rightarrow < A >, \alpha_1 \dots \alpha_n \rightarrow \alpha_1 + \dots \alpha_n$, onto and strictly increasing since all $\alpha_i > 0$. Now use Higman’s Theorem. \square

Hahn Fields

Let k be a field, Γ an ordered abelian group. Define $K = k((t^\Gamma))$ to be the set of all formal series $f(t) = \sum_{\gamma \in \Gamma} f_\gamma t^\gamma (f_\gamma \in k)$, whose **support** $\text{supp} f = \{\gamma \in \Gamma : f_\gamma \neq 0\}$ is **well-ordered**. Using (4.5), we can now define $f + g = \sum_{\gamma} (f_\gamma + g_\gamma) t^\gamma$, and $f * g = \sum_{\gamma} (\sum_{\alpha+\beta=\gamma} f_\alpha * g_\beta) t^\gamma$. K is an integral domain, and k includes into K by $a \rightarrow a * t^0$. We will show K is actually a field.

Week 5

November 3, 2014

We will now show that the Hahn field K defined last time is in fact a field. Define $v : K \setminus \{0\} \rightarrow \Gamma$ by

$$vF := \min \text{supp}(f).$$

We will use a profound but simple remark about the structure of K due (probably?) to Neumann: if $vF > 0$ (i.e., $\text{supp}(f) \subseteq \Gamma^{>0}$), then $\sum_{n=0}^{\infty} f^n$ makes sense as an element of K . Why? By (4.6), for any $\gamma \in \Gamma$ there are finitely many n such that $\gamma \in \text{supp}(f^n)$. By definition of multiplication in K , any $\gamma \in \text{supp}(f^n)$ is an element of $\langle \text{supp}(f) \rangle$. By the second part of (4.6), there are only finitely many such n .

Now write an arbitrary $g \in K \setminus \{0\}$ as $g = ct^\gamma(1 - f)$ where $c \in K \setminus \{0\}$, $\gamma \in \Gamma$, and $vF = 0$ (this is achieved by taking γ to be $\min \text{supp}(g)$). Then it can be checked that $g^{-1} = c^{-1}t^{-\gamma} \sum_{n=0}^{\infty} f^n$ works.

5 The ω^- map

Let $(\Gamma, \leq, +)$ be an ordered abelian group. Set $|\gamma| := \max\{\gamma, -\gamma\}$ for $\gamma \in \Gamma$. We say α, β are **archimedean equivalent** if there is some $n \geq 1$ such that $|\alpha| \leq n|\beta|$ and $|\beta| \leq n|\alpha|$. This is an equivalence relation on Γ , we write $\alpha \sim \beta$. Denote the equivalence classes $[\alpha] = \{\beta \in \Gamma : \beta \sim \alpha\}$. These equivalence classes $[\Gamma] = \{[\gamma] : \gamma \in \Gamma\}$ can be ordered by

$$[\alpha] < [\beta] \quad \text{if and only if} \quad \text{for all } n \geq 1, n|\alpha| < |\beta|.$$

We also write $\alpha \ll \beta$ or $\alpha = o(\beta)$ instead of $[\alpha] < [\beta]$. This defines a total order on $[\Gamma]$ with smallest element $[0]$.

This equivalence relation gives a coarse view of the ordered abelian group Γ .

Some properties:

1. $[-\alpha] = [\alpha]$.
2. $[\alpha + \beta] \leq \max\{[\alpha], [\beta]\}$ and equality holds if $[\alpha] \neq [\beta]$.
3. If $0 \leq \alpha \leq \beta$, then $[\alpha] \leq [\beta]$.

We say that Γ is **archimedean** if $[\Gamma] \setminus \{[0]\}$ is a singleton.

Lemma 5.1. *If Γ is archimedean and $\epsilon \in \Gamma^{>0}$, then there is a unique embedding $(\Gamma, \leq, +) \rightarrow (\mathbb{R}, \leq, +)$ with $\epsilon \mapsto 1$.*

The proof is easy, using Dedekind cuts.

Lemma 5.2. *Let $a \in \mathbf{No}$. Then there is a unique $x \in \mathbf{No}$ of minimal length with $a \sim x$.*

Proof. There is certainly an $x \in [a]$ of smallest length. Let $x \neq y$ with $x \sim a \sim y$. Put $z := x \wedge y$. Then $z \sim x \sim y$ and $l(z) < l(x)$ or $l(z) < l(y)$. \square

For each $b \in \mathbf{No}$, define a "canonical element" ω^b of "bth order of magnitude":

Definition 5.3. Assuming that ω^c for $c <_s b$ has been defined already, set

$$\omega^b := \{0, r\omega^{b_L} \mid s\omega^{b_R}\}$$

where r, s range over $\mathbb{R}^{>0}$ and $b = \{b_L \mid b_R\}$.

Lemma 5.4. *Suppose $\gamma \in \mathbf{On}$ and ω^b has been defined for all $b \in \mathbf{No}$ with $\ell(b) < \gamma$ such that:*

1. $0 < \omega^b$,
2. $b < c \Rightarrow \omega^b \ll \omega^c$.

Then (5.3) makes sense for $b \in \mathbf{No}$ with $\ell(b) \leq \gamma$ and (1), (2) above hold for all $b, c \in \mathbf{No}$ with $\ell(b), \ell(c) \leq \gamma$.

Proof. Suppose $\ell(b) = \gamma$. Then $\ell(b_L), \ell(b_R) < \gamma$, so $\omega^{b_L} \ll \omega^{b_R}$. Therefore $r\omega^{b_L} < s\omega^{b_R}$ for any $r, s \in \mathbb{R}^{>0}$. So $0 < s\omega^{b_R}$ for any $s \in \mathbb{R}^{>0}$. Hence ω^b is defined (i.e., this is actually a cut) and $\omega^b > 0$.

Suppose $b < c$ with lengths $\leq \gamma$. There are three cases: if $b <_s c$, then $b = c_L$, so $\omega^b \ll \omega^c$ by definition of ω^c . If $c <_s b$, then $c = b_R$, so $\omega^b \ll \omega^c$ by definition of ω^b . Otherwise, $b < b \wedge c < c$ and then by the two cases discussed before, $\omega^b \ll \omega^{b \wedge c} \ll \omega^c$. \square

When it comes to surreal numbers, it seems that a good definition has invariance under different representations.

Corollary 5.5. If $b = \{L \mid R\}$, then $\omega^b = \{0, \mathbb{R}^{>0} \cdot \omega^L \mid \mathbb{R}^{>0} \cdot \omega^R\}$.

The proof is an exercise using cofinality and inverse cofinality theorems.

Lemma 5.6. Let $a \in \mathbf{No}$. Then $a = \omega^b$ for some $b \in \mathbf{No}$ if and only if a is the element of minimal length of $[a]$.

Proof. Suppose $a = \omega^b = \{0, r\omega^{b_L} \mid s\omega^{b_R}\}$. If $a \sim x$, then $r\omega^{b_L} < x < s\omega^{b_R}$ for some $r, s \in \mathbb{R}^{>0}$ so $a \leq_s x$. This finishes one direction of the proof, the other will be done next time. \square

November 7, 2014

No class on Wednesday.

To finish the other direction of Lemma 5.6, we show that each $a \in \mathbf{No}$, $a > 0$, is \sim to some element of the form ω^b by induction on $\ell(a)$. Suppose $a = \{L \mid R\}$, with $0 \in L$. By induction hypothesis, every element of $L \cup R$ is \sim to some ω^b . Put

$$F := \{y \in \mathbf{No} : \exists a_L \in L : a_L \sim \omega^y\}$$

$$G := \{y \in \mathbf{No} : \exists a_R \in R : a_R \sim \omega^y\}.$$

Case 1. $F \cap G \neq \emptyset$.

Let $y \in F \cap G$. Then there are $a_L \in L$, $a_R \in R$ with $a_L \sim \omega^y \sim a_R$. Since $0 < a_L < a < a_R$, we get $a \sim \omega^y$.

Case 2. $F \cap G = \emptyset$.

It is easy to see that $F < G$. Now put $z := \{F \mid G\}$. Note that F and G are sets because the different ω^y are in different archimedean classes. We distinguish three cases:

Case 2a. $[\omega^x] \geq [a]$ for some $x \in F$.

Take $a_L \in L$ with $\omega^x \sim a_L$. Then $[a] = [\omega^x]$.

Case 2b. $[\omega^x] \leq [a]$ for some $x \in G$.

Then also $[a] = [\omega^x]$.

Case 2c. $[\omega^x] < [a] < [\omega^y]$ for all $x \in F$, $y \in G$.

We claim that $a = \omega^z$. To show this we prove that $(\{0\} \cup \mathbb{R}^{>0}\omega^F, \mathbb{R}^{>0}\omega^G)$ is cofinal in (L, R) . Let $a_L \in L \setminus \{0\}$. Then by induction hypothesis, there is $x \in F$ with $a_L \sim \omega^x$. So there is some $r \in \mathbb{R}^{>0}$ such that $r\omega^x \geq a_L$. Similarly for each $a_R \in R$ there is some $y \in G$ and $r \in \mathbb{R}^{>0}$ s.t. $r\omega^y \leq a_R$. \square

Lemma 5.7. The map $a \mapsto \omega^a$ is an embedding of ordered groups $(\mathbf{No}, +, \leq) \hookrightarrow (\mathbf{No}^{>}, \cdot, \leq)$.

Proof. By definition, $\omega^0 = \{0 \mid \emptyset\} = 1$. By induction on $\ell(a) \oplus \ell(b)$ we show that $\omega^a \omega^b = \omega^{a+b}$.

Let $a = \{a_L \mid a_R\}$, $b = \{b_L \mid b_R\}$, so $\omega^a = \{0, r\omega^{a_L} \mid s\omega^{a_R}\}$ and $\omega^b = \{0, r'\omega^{b_L} \mid s'\omega^{b_R}\}$, where r, s, r', s' range over $\mathbb{R}^{>0}$. Then

$$\omega^{a+b} = \{0, r\omega^{a_L+b_L}, r'\omega^{a_L+b_L} \mid s\omega^{a_R+b_R}, s'\omega^{a_R+b_R}\}.$$

Using the definition of multiplication and induction hypothesis, $\omega^a \cdot \omega^b$ has left part

$$\{0, r\omega^{a_L+b}, r'\omega^{b_L+a}, r\omega^{a_L+b} + r'\omega^{b_L+a} - rr'\omega^{a_L+b_L}, s\omega^{a_R+b} + s'\omega^{b_R+a} - ss'\omega^{a_R+b_R}\}$$

and right part

$$s\omega^{a_R+b}, s'\omega^{b_R+a}, r\omega^{a_L+b} + s'\omega^{b_R+a} - rs'\omega^{a_L+b_R}, s\omega^{a_R+b} + r'\omega^{b_L+a} - r's\omega^{a_R+b_L}\}$$

We will show that these two cuts are mutually cofinal, proving the lemma. Note that the elements defining ω^{a+b} also appear in the cut for $\omega^a\omega^b$.

Also,

1. $r\omega^{a_L+b} + r'\omega^{b_L+a} - rr'\omega^{a_L+b_L} \leq (r + r')\omega^{\max(a_L+b, a+b_L)}$ (a term appearing in the cut for ω^{a+b}).
2. $s\omega^{a_R+b} + s'\omega^{a+b_R} - ss'\omega^{a_R+b_R} < 0$. (The third term of the LHS has the highest archimedean class.)
3. $r\omega^{a_L+b} + s'\omega^{b_R+a} - rs'\omega^{a_L+b_R} > s''\omega^{b_R+a}$ for any $s'' \in \mathbb{R}$ with $0 < s'' < s'$. (The second term of the LHS has the highest archimedean class.)
4. $s\omega^{a_R+b} + r'\omega^{b_L+a} - r's\omega^{a_R+b_L} > s''\omega^{a_R+b}$ for any $0 < s'' < s$. (The first term of the LHS has the highest archimedean class.)

□

That was messy, but nice because it all fell out of the definition of the ω^- map.

We now check that ordinal exponentiation agrees with the ω^- map.

Lemma 5.8. *For $a \in \mathbf{On}$, $\omega^a \in \mathbf{No}$ is the same as the ordinal ω^a (ordinal exponentiation).*

Proof. Write $\omega \uparrow a$ for ordinal exponentiation. By induction on $a \in \mathbf{On}$, we show that $\omega^a = \omega \uparrow a$. The base case was already done. Let $a = \{a_L \mid \emptyset\}$. Then using the induction hypothesis,

$$\begin{aligned} \omega^a &= \{0, r\omega^{a_L} \mid \emptyset\} = \{0, r\omega \uparrow a_L \mid \emptyset\} \\ &= \omega \uparrow a, \end{aligned}$$

using the definition of ordinal exponentiation for the last equality. □

6 The Normal Form

Let $K = \mathbb{R}((t^{\mathbb{N} \times}))$ be the Hahn field and set $x := \frac{1}{t}$. We think of the elements of K as formal series in x :

$$f(x) = \sum_{i < \alpha} f_i x^{a_i}$$

where $\alpha \in \mathbf{On}$, (a_i) is a strictly decreasing sequence in \mathbf{No} , and $f_i \in \mathbb{R} \setminus \{0\}$. So α is the order-type of $\text{supp}(f)$, which we will denote by $\ell(f)$ (the agreement of the choice of this notation with the length of a surreal number is not a coincidence). We turn K into an ordered field such that $f > 0$ iff $f \neq 0$ and $f_0 > 0$. We will define an ordered field isomorphism between K and \mathbf{No} , which will give a normal form for elements of \mathbf{No} generalizing the Cantor normal form.

Week 6

Notes by Anton Bobkov

Monday, November 10, 2014

We define a map which will eventually be proven to be an ordered field isomorphism.

$$K = \mathbb{R}((t^{\mathbf{No}})) \xrightarrow{\sim} \mathbf{No}$$

We have an element written as

$$f = \sum_{\gamma \in \mathbf{No}} f_{\gamma} t^{\gamma}$$

$$\text{supp}(f) = \{\gamma : f_{\gamma} \neq 0\}$$

where $\text{supp}(f)$ is a well-ordered subset. Now let $x = t^{-1}$ and write

$$f(x) = \sum_{i < \alpha} f_i x^{a_i}$$

where $(a_i)_{i < \alpha}$ is strictly decreasing in \mathbf{No} , α ordinal and $f_i \in \mathbb{R}$ for $i < \alpha$. Also define $l(f(x))$ to be the order type of $\text{supp}(f)$ (which may be smaller than α as we allow zero coefficients).

==== Question ==== What is the relationship of what we are going to do with Kaplansky's results from valuation theory?

Theorem 6.1. For $f(x) = \sum_{i < \alpha} f_i x^{a_i}$ define $\sum_{i < \alpha} f_i \omega^{a_i} = f(\omega)$ recursively on α :
When $\alpha = \beta + 1$ is a successor:

$$\sum_{i < \alpha} f_i \omega^{a_i} = \left(\sum_{i < \beta} f_i \omega^{a_i} \right) + f_{\beta} \omega^{a_{\beta}}$$

When α is a limit ordinal:

$$\sum_{i < \alpha} f_i \omega^{a_i} = \{L \mid R\}$$

$$L_f = \left\{ \sum_{i < \beta} f_i \omega^{a_i} + (f_{\beta} - \epsilon) \omega^{a_{\beta}} : \beta < \alpha, \epsilon \in \mathbb{R}^{>0} \right\}$$

$$R_f = \left\{ \sum_{i < \beta} f_i \omega^{a_i} + (f_{\beta} + \epsilon) \omega^{a_{\beta}} : \beta < \alpha, \epsilon \in \mathbb{R}^{>0} \right\}$$

Simultaneously with this definition we prove the following statements by induction:
"Inequality." For

$$f(x) = \sum_{i < \alpha} f_i x^{a_i}$$

$$g(x) = \sum_{i < \alpha} g_i x^{a_i}$$

we have $f(x) > g(x) \Rightarrow f(\omega) > g(\omega)$ "Tail property." if $\gamma < \kappa < \alpha$

$$\left| \sum_{i < \alpha} f_i \omega^{a_i} - \sum_{i < \kappa} f_i \omega^{a_i} \right| < \omega^{a_{\gamma}}$$

Proof of inequality. Suppose we have

$$f(x) = \sum_{i < \alpha} f_i x^{a_i}$$

$$g(x) = \sum_{i < \alpha} g_i x^{a_i}$$

with $f(x) < g(x)$

Choose γ smallest such that $f_\gamma \neq g_\gamma$. It has to be that $f_\gamma > g_\gamma$. Also $f(x) \upharpoonright_\gamma = g(x) \upharpoonright_\gamma$

Case 1: $\alpha = \beta + 1$

$$f(x) = f(x) \upharpoonright_\beta + f_\beta x^{a_\beta}$$

$$g(x) = g(x) \upharpoonright_\beta + g_\beta x^{a_\beta}$$

Suppose $\gamma = \beta$. Then $\bar{f}(x) = \bar{g}(x)$, $\bar{f}(\omega) = \bar{g}(\omega)$, so compute

$$\begin{aligned} f(\omega) - g(\omega) &= \\ &= f(\omega) \upharpoonright_\beta + f_\beta \omega^{a_\beta} - g(\omega) \upharpoonright_\beta - g_\beta \omega^{a_\beta} \\ &= f_\beta \omega^{a_\beta} - g_\beta \omega^{a_\beta} \\ &= (f_\beta - g_\beta) \omega^{a_\beta} > 0 \end{aligned}$$

Now suppose $\gamma < \beta$.

Group the terms

$$\begin{aligned} f(\omega) &= h(\omega) + f_\gamma \omega^{a_\gamma} + f^* + f_\beta \omega^{a_\beta} \\ g(\omega) &= h(\omega) + g_\gamma \omega^{a_\gamma} + g^* + g_\beta \omega^{a_\beta} \end{aligned}$$

where

$$\begin{aligned} h(\omega) &= f(\omega) \upharpoonright_\gamma = g(\omega) \upharpoonright_\gamma \\ f^* &= f(\omega) \upharpoonright_\beta - f(\omega) \upharpoonright_{\gamma+1} \\ g^* &= g(\omega) \upharpoonright_\beta - g(\omega) \upharpoonright_{\gamma+1} \end{aligned}$$

Then we have by tail property $f^* \ll x^{a_\gamma}$ and $g^* \ll x^{a_\gamma}$. Compute

$$f(\omega) - g(\omega) = (f_\gamma - g_\gamma) \omega^{a_\gamma} + (f^* - g^*) + (f_\beta - g_\beta) \omega^{a_\beta}$$

We have $f_\gamma > g_\gamma$. All f^* , g^* and $(f_\beta - g_\beta) \omega^{a_\beta}$ are $\ll x^{a_\gamma}$. Thus $f(\omega) - g(\omega) > 0$ as needed.

Case 2: α is a limit ordinal.

$f(\omega)$ and $g(\omega)$ are defined as

$$\begin{aligned} f(\omega) &= \{L_f \mid R_f\} \\ g(\omega) &= \{L_g \mid R_g\} \end{aligned}$$

Recall that

$$\begin{aligned} L_f &= \left\{ \sum_{i < \beta} f_i \omega^{a_i} + (f_\beta - \epsilon) \omega^{a_\beta} : \beta < \alpha, \epsilon \in \mathbb{R}^{>0} \right\} \\ R_g &= \left\{ \sum_{i < \beta} g_i \omega^{a_i} + (g_\beta + \epsilon) \omega^{a_\beta} : \beta < \alpha, \epsilon \in \mathbb{R}^{>0} \right\} \end{aligned}$$

Pick any β with $\gamma < \beta < \alpha$ and $\epsilon \in \mathbb{R}^{>0}$, and pick limit elements $\bar{f}(\omega) \in L_f$ and $\bar{g}(\omega) \in R_g$ corresponding to β, ϵ .

Then $\bar{f}(x) < \bar{g}(x)$ as first coefficient where they differ is x^{a_γ} and $f_\gamma > g_\gamma$. Thus by inductive hypothesis $\bar{f}(\omega) < \bar{g}(\omega)$. As choice of those was arbitrary we have $L_f < R_g$ so $f(\omega) > g(\omega)$. \square

Proof of tail property. It is easy to see that statement holds for all $\gamma < \kappa < \alpha$ iff it holds for all $\gamma < \kappa \leq \alpha$.

Case 1: $\alpha = \beta + 1$.

Suppose we have $\gamma < \kappa < \alpha$, then $\gamma < \kappa \leq \beta$ and induction hypothesis applies.

$$\begin{aligned} \sum_{i < \alpha} f_i \omega^{a_i} - \sum_{i < \kappa} f_i \omega^{a_i} = \\ \left[\sum_{i < \beta} f_i \omega^{a_i} - \sum_{i < \kappa} f_i \omega^{a_i} \right] + f_\alpha \omega^{a_\alpha} \end{aligned}$$

Expression $[\dots]$ is $<< \omega^{a_\gamma}$ by induction hypothesis. $f_\alpha \omega^{a_\alpha} << \omega^{a_\gamma}$ as $a_\alpha < a_\gamma$. Thus the entire sum is $<< \omega^{a_\gamma}$ as needed.

Case 2: α is a limit ordinal.

Write definitions of $f(\omega)$ using κ

$$\begin{aligned} f(\omega) &= \{L_f \mid R_f\} \\ F(\omega) &= f(\omega) \upharpoonright_\kappa = \sum_{i < \kappa} f_i \omega^{a_i} \end{aligned}$$

$$\begin{aligned} L_f &= \left\{ \sum_{i < \beta} f_i \omega^{a_i} + (f_\beta - \epsilon) \omega^{a_\beta} : \beta < \alpha, \epsilon \in \mathbb{R}^{>0} \right\} \\ R_f &= \left\{ \sum_{i < \beta} f_i \omega^{a_i} + (f_\beta + \epsilon) \omega^{a_\beta} : \beta < \alpha, \epsilon \in \mathbb{R}^{>0} \right\} \end{aligned}$$

Pick any β with $\kappa < \beta < \alpha$ and $\epsilon \in \mathbb{R}^{>0}$, and pick limit elements $\bar{l}(\omega) \in L_f$ and $\bar{r}(\omega) \in R_f$ corresponding to β, ϵ .

By induction hypothesis we have

$$\begin{aligned} \bar{l}(\omega) - F(\omega) &= \bar{l}(\omega) - \bar{l}(\omega) \upharpoonright_\kappa << \omega^{a_\kappa} \\ \bar{r}(\omega) - F(\omega) &= \bar{r}(\omega) - \bar{r}(\omega) \upharpoonright_\kappa << \omega^{a_\kappa} \end{aligned}$$

$$l(\omega) \leq f(\omega) \leq r(\omega)$$

$$l(\omega) - F(\omega) \leq f(\omega) - F(\omega) \leq r(\omega) - F(\omega)$$

Thus $f(\omega) - F(\omega) << \omega^{a_\kappa}$ as it is between two elements that are $<< \omega^{a_\kappa}$. \square

Proof of well-definiteness. We also need to check that the function is well-defined. For $f(x)$ define its reduced form, where we only keep non-zero coefficients.

$$f(x) = \sum_{i < \alpha} f_i \omega^{a_i}$$

$$\bar{f}(x) = \sum_{j < \alpha'} f'_j \omega^{a'_j}$$

We need to check that $f(\omega) = \bar{f}(\omega)$

Case 1: $\alpha = \beta + 1$

$$f(\omega) = g(\omega) + f_\beta \omega^{a_\beta}$$

$$g(x) = \sum_{i < \beta} f_i \omega^{a_i}$$

$$g(\omega) = \bar{g}(\omega)$$

If $f_\beta = 0$ then $\bar{f}(x) = \bar{g}(x)$ and $f(\omega) = g(\omega)$ so $f(\omega) = g(\omega) = \bar{g}(\omega) = \bar{f}(\omega)$ as needed. Suppose $f_\beta \neq 0$. Then $\bar{f}(x) = \bar{g}(x) + f_\beta x^{a_\beta}$.

$$f(\omega) = g(\omega) + f_\beta \omega^{a_\beta} = \bar{g}(\omega) + f_\beta \omega^{a_\beta} = \bar{f}(\omega)$$

Case 2: α is a limit and non-zero coefficients are cofinal in α .

In this case both $f(x)$ and $\bar{f}(x)$ have limit ordinals in their definitions. Moreover

$$L_{\bar{f}} \subseteq L_f$$

$$R_{\bar{f}} \subseteq R_f$$

and are cofinal. Thus $f(\omega) = \bar{f}(\omega)$.

Case 3: α is a limit and for some $\gamma < \alpha$

$$\gamma \leq \beta < \alpha \Rightarrow f_\beta = 0$$

$$g(x) = \sum_{i < \gamma} f_i x^{a_i}$$

$$L_f^* = \left\{ \sum_{i < \beta} f_i \omega^{a_i} + (f_\beta - \epsilon) \omega^{a_\beta} : \gamma < \beta < \alpha, \epsilon \in \mathbb{R}^{>0} \right\}$$

$$= \{ g(\omega) - \epsilon \omega^{a_\beta} : \gamma < \beta < \alpha, \epsilon \in \mathbb{R}^{>0} \}$$

$$R_f^* = \left\{ \sum_{i < \beta} f_i \omega^{a_i} + (f_\beta + \epsilon) \omega^{a_\beta} : \gamma < \beta < \alpha, \epsilon \in \mathbb{R}^{>0} \right\}$$

$$= \{ g(\omega) + \epsilon \omega^{a_\beta} : \gamma < \beta < \alpha, \epsilon \in \mathbb{R}^{>0} \}$$

We have

$$L_f^* \subseteq L_f$$

$$R_f^* \subseteq R_f$$

and are cofinal. $\{L_f^* - g(\omega) \mid R_f^* - g(\omega)\} = 0$ as left side is negative and right side is positive. Thus $f(\omega) = \{L_f^* \mid R_f^*\} = g(\omega)$. As $\gamma < \alpha$ this case is covered by induction. \square

Wednesday, November 12, 2014

Lemma 6.2. $l(f(\omega)) \geq l(f(x))$

Proof. Suppose $\beta < \alpha$. Then the elements used to define $\sum_{i < \omega \cdot \beta}(\dots)$ also appear in the cut for $\sum_{i < \omega \cdot \alpha}(\dots) = f(\omega)$. Thus by uniqueness of the normal form.

$$l\left(\sum_{i < \omega \cdot \beta}(\dots)\right) < l(f(\omega))$$

So the map $\phi(\beta) = l(\sum_{i < \omega \cdot \beta}(\dots))$ is strictly increasing. Any strictly increasing map ϕ on an initial segment of \mathbf{On} satisfies $\phi(\beta) \geq \beta$. \square

Lemma 6.3. *The map*

$$\begin{aligned} K &\rightarrow \mathbf{No} \\ f(x) &\mapsto f(\omega) \end{aligned}$$

is onto.

Proof. Let $a \in \mathbf{No}, a \neq 0$. By (5.6) there is a unique $b \in \mathbf{No}$ such that $[a] = [\omega^b]$. Put

$$S = \{s \in \mathbb{R} : s\omega^b \leq a\}$$

Then $S \neq \emptyset$ and bounded from above. Put $r = \sup S \in \mathbb{R}$. Then

$$(r + \epsilon)\omega^b > a > (r - \epsilon)\omega^b$$

for all $\epsilon \in \mathbb{R}^{>0}$ thus

$$|a - r\omega^b| << \omega^b \quad (*)$$

Note $r \neq 0$; r, b subject to $(*)$ are unique.

We set $\text{lt}(a) = r\omega^b$

Towards a contradiction assume that a is not in the image of $f(x) \mapsto f(\omega)$. We shall inductively define a sequence $(a_i, f_i)_{i \in \mathbf{On}}$ where

1. $a_i \in \mathbf{No}$ is strictly decreasing; $f_i \in \mathbb{R} - \{0\}$
2. $f_\alpha \omega^{a_\alpha} = \text{lt}(a - \sum_{i < \alpha} f_i \omega^{a_i})$ for all $\alpha \in \mathbf{On}$

Case 1: $\alpha = \beta + 1$

Take (a_α, f_α) so that

$$f_\alpha \omega^{a_\alpha} = \text{lt}\left(a - \sum_{i < \alpha}(\dots)\right)$$

By inductive hypothesis, if $\beta < \alpha$

$$\begin{aligned} f_\beta \omega^{a_\beta} &= \text{lt}\left(a - \sum_{i < \beta}(\dots)\right) \\ \Rightarrow f_\alpha \omega^{a_\alpha} &= \text{lt}\left(\left(a - \sum_{i < \beta}(\dots)\right) - f_\beta \omega^{a_\beta}\right) \\ &<< \omega^{a_\beta} \text{ by } (*) \\ \Rightarrow a_\alpha &< a_\beta \end{aligned}$$

Case 2: α limit

Take (a_α, f_α) as above. Let $\beta < \alpha$; to show $a_\alpha < a_\beta$. We have

$$a - \sum_{i \leq \beta} f_i \omega^{a_i} = \left(a - \sum_{i < \beta} f_i \omega^{a_i} \right) - f_\beta \omega^{a_\beta} << \omega^{a_\beta}$$

By the tail property

$$\begin{aligned} & \sum_{i < \alpha} (\dots) - \sum_{i \leq \beta} (\dots) << \omega^{a_\beta} \\ \Rightarrow & a - \sum_{i < \alpha} (\dots) << \omega^{a_\beta} \\ \Rightarrow & \text{lt} \left(a - \sum_{i < \alpha} (\dots) \right) << \omega^{a_\beta} \\ \Rightarrow & a_\alpha < a_\beta \end{aligned}$$

This completes the induction. Note that we showed that if α is a limit then $a - \sum_{i < \alpha} (\dots) << \omega^{a_\beta}$ for all $\beta < \alpha$.

So if $\{L \mid R\}$ is the cut used to define $\sum_{i < \alpha} (\dots)$ then $L < a < R$. Let $\alpha = \omega \cdot \alpha'$. Hence

$$l(a) > l \left(\sum_{i < \omega \cdot \alpha'} (\dots) \right) \geq \alpha'$$

by (6.1). So $l(a)$ is bigger than all limits - contradiction. \square

Lemma 6.4. *Let $r \in \mathbb{R}, a \in \mathbf{No}$. Then*

$$r\omega^a = \{(r - \epsilon)\omega^a \mid (r + \epsilon)\omega^a\}$$

where ϵ ranges over $\mathbb{R}^{>0}$.

Proof.

$$\begin{aligned} r &= \{r - \epsilon \mid r + \epsilon\} \\ \omega^a &= \{0, s\omega^{a_L} \mid t\omega^{a_R}\} \text{ where } s, t \in \mathbb{R}^{>0} \end{aligned}$$

$$\begin{aligned} r\omega^a &= \{(r - \epsilon)\omega^a, (r - \epsilon)\omega^a + \epsilon s\omega^{a_L}, \\ & \quad (r + \epsilon)\omega^a - \epsilon t\omega^{a_R} \mid \\ & \quad (r + \epsilon)\omega^a, (r + \epsilon)\omega^a - \epsilon s\omega^{a_R}, \\ & \quad (r - \epsilon)\omega^a + \epsilon t\omega^{a_L}\} \end{aligned}$$

Now use $\omega^{a_L} << \omega^a << \omega^{a_R}$ and cofinality. \square

Friday, November 14, 2014

Corollary 6.5.

$$\sum_{i \leq \alpha} f_i \omega^{a_i} = \left\{ \sum_{i < \alpha} f_i \omega^{a_i} + (f_i - \epsilon)\omega^{a_\alpha} \mid \sum_{i < \alpha} f_i \omega^{a_i} + (f_i + \epsilon)\omega^{a_\alpha} \right\}$$

Proof. **Case 1:** α is a limit

$$\begin{aligned}
\sum_{i \leq \alpha} f_i \omega^{a_i} &= \sum_{i < \alpha} f_i \omega^{a_i} + f_\alpha \omega^{a_\alpha} = \\
&\stackrel{(6.4)}{=} \left\{ \sum_{i < \beta} f_i \omega^{a_i} + (f_\beta - \epsilon) \omega^{a_\beta} \mid \sum_{i < \beta} f_i \omega^{a_i} + (f_\beta + \epsilon) \omega^{a_\beta} \right\}_{\beta < \alpha, \epsilon \in \mathbb{R}^{>0}} + \{(r - \epsilon) \omega^\alpha \mid (r + \epsilon) \omega^\alpha\} = \\
&= \left\{ \sum_{i \leq \beta} f_i \omega^{a_i} - \epsilon \omega^{a_\beta} + f_\alpha \omega^{a_\alpha}, \sum_{i < \alpha} f_i \omega^{a_i} + (f_\alpha - \epsilon) \omega^{a_\alpha} \mid \dots \right\} = \\
&\stackrel{\text{cofinality}}{=} \left\{ \sum_{i < \alpha} f_i \omega^{a_i} + (f_i - \epsilon) \omega^{a_\alpha} \mid \dots \right\}
\end{aligned}$$

Case 2: $\alpha + 1$

$$\begin{aligned}
\sum_{i \leq \alpha+1} f_i \omega^{a_i} &= \sum_{i \leq \alpha} f_i \omega^{a_i} + f_{\alpha+1} \omega^{a_{\alpha+1}} = \\
&\text{(by (6.4) and induction hypothesis)} \\
&= \left\{ \sum_{i \leq \alpha} f_i \omega^{a_i} + (f_\alpha - \epsilon) \omega^{a_\alpha} \mid \dots \right\} + \{(f_{\alpha+1} - \epsilon) \omega^{a_{\alpha+1}} \mid \dots\} = \\
&= \left\{ \sum_{i < \alpha} f_i \omega^{a_i} + (f_\alpha - \epsilon) \omega^{a_\alpha} + f_{\alpha+1} \omega^{a_{\alpha+1}}, \sum_{i \leq \alpha} f_i \omega^{a_i} + (f_{\alpha+1} - \epsilon) \omega^{a_{\alpha+1}} \mid \dots \right\}
\end{aligned}$$

and again we are done by cofinality. □

Math 285D Notes: 11/17, 11/19, 11/21

Tyler Arant

Lemma 6.6 (Associativity). *Let $\alpha, \beta \in \mathbf{On}$, $(a_i)_{i < \alpha + \beta}$ be a strictly decreasing sequence in \mathbf{No} and $f_i \in \mathbb{R}$ for $i < \alpha + \beta$. Then,*

$$\sum_{i < \alpha + \beta} f_i \omega^{a_i} = \sum_{i < \alpha} f_i \omega^{a_i} + \sum_{j < \beta} f_{\alpha + j} \omega^{a_{\alpha + j}}.$$

Proof. We proceed by induction on β . In the case that $\beta = \gamma + 1$ is a successor ordinal, we have

$$\begin{aligned} \sum_{i < \alpha + (\gamma + 1)} f_i \omega^{a_i} &= \sum_{i < \alpha + \gamma} f_i \omega^{a_i} + f_{\alpha + \gamma} \omega^{a_{\alpha + \gamma}} \\ &= \sum_{i < \alpha} f_i \omega^{a_i} + \sum_{j < \gamma} f_{\alpha + j} \omega^{a_{\alpha + j}} + f_{\alpha + \gamma} \omega^{a_{\alpha + \gamma}} \\ &= \sum_{i < \alpha} f_i \omega^{a_i} + \sum_{j < \gamma + 1} f_{\alpha + j} \omega^{a_{\alpha + j}}, \end{aligned}$$

where the first and third equality use the definition of \sum and the second equality uses the induction hypothesis.

In the case where β is a limit ordinal, we let

$$\{L|R\} = \sum_{j < \beta} f_{\alpha + j} \omega^{a_{\alpha + j}}.$$

Using the definition of addition between surreal numbers and a simple cofinality argument, we obtain

$$\sum_{i < \alpha} f_i \omega^{a_i} + \sum_{j < \beta} f_{\alpha + j} \omega^{a_{\alpha + j}} = \left\{ \sum_{i < \alpha} f_i \omega^{a_i} + L \mid \sum_{i < \alpha} f_i \omega^{a_i} + R \right\}.$$

A typical element of this cut is

$$\sum_{i < \alpha} f_i \omega^{a_i} + \sum_{j \leq \gamma} f_{\alpha + j} \omega^{a_{\alpha + j}} - \varepsilon \omega^{a_{\alpha + \gamma}} \quad (\gamma < \beta, \varepsilon \in \mathbb{R}^{>0}).$$

By inductive hypothesis, this equals

$$\sum_{i < \alpha + \gamma} f_i \omega^{a_i} - \varepsilon \omega^{a_{\alpha + \gamma}}.$$

But these elements are cofinal in the cut defining $\sum_{i < \alpha + \beta} f_i \omega^{a_i}$; hence, the claim follows by cofinality. \square

Proposition 6.7. Let $\alpha \in \mathbf{On}$, $(a_i)_{i < \alpha}$ be a strictly decreasing sequence in \mathbf{No} and $f_i, g_i \in \mathbb{R}$ for $i < \alpha$. Then,

$$\sum_{i < \alpha} f_i \omega^{a_i} + \sum_{i < \alpha} g_i \omega^{a_i} = \sum_{i < \alpha} (f_i + g_i) \omega^{a_i}.$$

Proof. We proceed by induction on α . If $\alpha = \beta + 1$ is a successor, then

$$\begin{aligned}
\sum_{i < \beta+1} f_i \omega^{a_i} + \sum_{i < \beta+1} g_i \omega^{a_i} &= \left(\sum_{i < \beta} f_i \omega^{a_i} + f_\beta \omega^{a_\beta} \right) + \left(\sum_{i < \beta} g_i \omega^{a_i} + g_\beta \omega^{a_\beta} \right) \\
&= \left(\sum_{i < \beta} f_i \omega^{a_i} + \sum_{i < \beta} g_i \omega^{a_i} \right) + (f_\beta \omega^{a_\beta} + g_\beta \omega^{a_\beta}) \\
&= \sum_{i < \beta} (f_i + g_i) \omega^{a_i} + (f_\beta + g_\beta) \omega^{a_\beta} \\
&= \sum_{i < \beta+1} (f_i + g_i) \omega^{a_i},
\end{aligned}$$

where the third equality uses the induction hypothesis.

Now suppose α is a limit. One type of element from the left-hand-side of the cut defining $\sum_{i < \alpha} f_i \omega^{a_i} + \sum_{i < \alpha} g_i \omega^{a_i}$ is of the form

$$\sum_{i \leq \beta} f_i \omega^{a_i} - \varepsilon \omega^{a_\beta} + \sum_{i < \alpha} g_i \omega^{a_i}$$

or of the form

$$\sum_{i < \alpha} f_i \omega^{a_i} + \sum_{i \leq \beta} g_i \omega^{a_i} - \varepsilon \omega^{a_\beta}.$$

We have

$$\begin{aligned}
\sum_{i \leq \beta} f_i \omega^{a_i} - \varepsilon \omega^{a_\beta} + \sum_{i < \alpha} g_i \omega^{a_i} &= \sum_{i \leq \beta} f_i \omega^{a_i} + \sum_{i \leq \beta} g_i \omega^{a_i} + \sum_{\beta < i < \alpha} g_i \omega^{a_i} - \varepsilon \omega^{a_\beta} \\
&= \sum_{i \leq \beta} (f_i + g_i) \omega^{a_i} + \sum_{\beta < i < \alpha} g_i \omega^{a_i} - \varepsilon \omega^{a_\beta},
\end{aligned}$$

where the first equality follows from (6.6) and the second equality uses the inductive hypothesis. But this is mutually cofinal with

$$\sum_{i \leq \beta} (f_i + g_i) \omega^{a_i} - \varepsilon \omega^{a_\beta}.$$

Similarly if we start with $\sum_{i < \alpha} f_i \omega^{a_i} + \sum_{i \leq \beta} g_i \omega^{a_i} - \varepsilon \omega^{a_\beta}$. □

Lemma 6.8. Let $\alpha \in \mathbf{On}$, $(a_i)_{i < \alpha}$ be a strictly decreasing sequence in \mathbf{No} , $b \in \mathbf{No}$, and $f_i \in \mathbb{R}$ for $i < \alpha$. Then,

$$\left(\sum_{i < \alpha} f_i \omega^{a_i} \right) \omega^b = \sum_{i < \alpha} f_i \omega^{a_i + b}.$$

Note that the sequence $(a_i + b)_i$ is also strictly decreasing.

Proof. We proceed by induction on α . If $\alpha = \beta + 1$, then

$$\begin{aligned}
\left(\sum_{i < \beta+1} f_i \omega^{a_i} \right) \omega^b &= \left(\sum_{i < \beta} f_i \omega^{a_i} + f_\beta \omega^{a_\beta} \right) \omega^b \\
&= \left(\sum_{i < \beta} f_i \omega^{a_i} \right) \omega^b + f_\beta \omega^{a_\beta} \cdot \omega^b \\
&= \sum_{i < \beta} f_i \omega^{a_i+b} + f_\beta \omega^{a_\beta+b} \\
&= \sum_{i < \beta+1} f_i \omega^{a_i+b},
\end{aligned}$$

where the third equality uses the inductive hypothesis.

Now suppose α is a limit. Recall that, by their respective definitions,

$$\omega^b = \{0, s\omega^{b'} \mid t\omega^{b''}\}$$

and

$$\sum_{i < \alpha} f_i \omega^{a_i} = \left\{ \sum_{i \leq \beta} f_i \omega^{a_i} - \varepsilon \omega^{a_\beta} : \beta < \alpha, \varepsilon \in \mathbb{R}^{>0} \mid \sum_{i \leq \beta} f_i \omega^{a_i} + \varepsilon \omega^{a_\beta} : \beta < \alpha, \varepsilon \in \mathbb{R}^{>0} \right\}.$$

Set $d := \sum_{i < \alpha} f_i \omega^{a_i}$ and let d', d'' be elements from the left and right-hand sides, respectively, of the defining cut determined by the same choice of ε . Note that

$$d - d' = \varepsilon \omega^{a_\beta} + c', \quad \text{where } c' \ll \omega^{a_\beta},$$

and

$$d'' - d = \varepsilon \omega^{a_\beta} + c'', \quad \text{where } c'' \ll \omega^{a_\beta}.$$

It follows that

$$\varepsilon_1 \omega^{a_\beta} < d - d', d'' - d < \varepsilon_2 \omega^{a_\beta}, \quad \text{for all } \varepsilon_1 < \varepsilon < \varepsilon_2 \text{ in } \mathbb{R}, \quad (*)$$

where ε is given by the choice of d', d'' . Now,

$$\begin{aligned}
d\omega^b &= \{d' \mid d''\} \cdot \{0, s\omega^{b'} \mid t\omega^{b''}\} \\
&= \{d'\omega^b, d'\omega^b + (d - d')s\omega^{b'}, \underline{d''\omega^b - (d'' - d)t\omega^{b''}} \mid \\
&\quad \underline{d''\omega^b}, \underline{d'\omega^b + (d - d')t\omega^{b''}}, d''\omega^b - (d'' - d)s\omega^{b'}\},
\end{aligned}$$

and we claim that the underlined terms are superfluous; in particular,

$$(1) \quad d''\omega^b - (d'' - d)t\omega^{b''} \leq d'\omega^b + (d - d')s\omega^{b'};$$

$$(2) \quad d''\omega^b - (d'' - d)s\omega^{b'} \leq d'\omega^b + (d - d')t\omega^{b''}.$$

To show (1), note that $\omega^{b''} \gg \omega^b \gg \omega^{b'}$ implies

$$(d'' - d)t\omega^{b''} + (d - d')s\omega^{b'} \geq \varepsilon_1 \omega^{a_\beta} t\omega^{b''} > 2\varepsilon_2 \omega^{a_\beta} \omega^b \geq (d'' - d)\omega^b.$$

The verification for (2) is similar. So, by (1), (2) and confinality,

$$d\omega^b = \{d'\omega^b, d'\omega^b + (d - d')s\omega^{b'} \mid d''\omega^b, d''\omega^b - (d'' - d)s\omega^{b'}\}.$$

We claim that we can further simplify this to

$$d\omega^b = \{d'\omega^b \mid d''\omega^b\},$$

then we are done by inductive hypothesis. Let now $\varepsilon_{1,2} \in \mathbb{R}^{>0}$ with $\varepsilon_1 < \varepsilon < \varepsilon_2$ and

$$d'_1 = \sum_{i \geq \beta} f_i \omega^{a_i} - \varepsilon_1 \omega^{a_\beta}, \quad d''_1 = \sum_{i \geq \beta} f_i \omega^{a_i} + \varepsilon_1 \omega^{a_\beta}.$$

We claim that

$$d'_1 \omega^b > d' \omega^b + (d - d') s \omega^{b'}, \quad d''_1 \omega^b < d'' \omega^b - (d'' - d) s \omega^{b'}.$$

Notice that the first claim holds if and only if $(d'_1 - d') \omega^b > (d - d') s \omega^{b'}$. But this inequality holds since

$$(d'_1 - d) \omega^b = (\varepsilon - \varepsilon_2) \omega^{a_\beta} \omega^b > \varepsilon_2 s \omega^{a_\beta} \omega^{b'} \geq (d - d') s \omega^{b'},$$

where the first inequality holds since $\omega^b \gg \omega^{b'}$ and the second inequality holds by (*). The second part of the claim is proved similarly. \square

Proposition 6.9. Let $\alpha, \beta \in \mathbf{On}$, $(a_i)_{i < \alpha}$, $(b_j)_{j < \beta}$ be strictly decreasing sequences in \mathbf{No} , and $f_i, g_i \in \mathbb{R}$ for $i < \alpha$. Then,

$$\left(\sum_{i < \alpha} f_i \omega^{a_i} \right) \left(\sum_{j < \beta} g_j \omega^{b_j} \right) = \sum_{i < \alpha, j < \beta} f_i g_j \omega^{a_i + b_j}.$$

Proof. If either α or β are successor ordinals, we verify the proposition by using the inductive hypothesis and lemma (6.8). Thus, we only need to consider the case where α and β are both limits. Put

$$f = \sum_{i < \alpha} f_i X^{a_i}, \quad g = \sum_{j < \beta} g_j X^{a_j} \in K.$$

Recall that the typical element in the cut of $f(\omega) \cdot g(\omega)$ is

$$f(\omega)g(\omega)_{**} + f(\omega)_*g(\omega) - f(\omega)_*g(\omega)_{**}, \quad (\dagger)$$

where $*, **$ are either L or R . Moreover, this element is $< f(\omega)g(\omega)$ if and only if $(*, **) = (L, L)$ or (R, R) . Take $f_*, g_{**} \in K$ such that $f_*(\omega) = f(\omega)_*$ and $g_{**}(\omega) = g(\omega)_{**}$. Then, by inductive hypothesis, \dagger equals

$$(f \cdot g)(\omega) - ((f - f_*)(g - g_{**}))(\omega).$$

For example,

$$f_* = \sum_{i < \gamma} f_i X^{a_i} + (f_\gamma \pm \varepsilon_1) X^{a_\gamma}, \quad \gamma < \alpha$$

implies $f - f_* = \pm \varepsilon_1 X^{a_\gamma} + h_1$, where all the terms in h_1 have degree $> \gamma$. Similarly, $g - g_{**} = \pm \varepsilon_2 X^{b_\delta} + h_2$, where $\delta < \beta$ and all the terms in h_2 have degree $> \delta$. Thus,

$$(f - f_*)(g - g_{**}) = \pm \varepsilon_1 \varepsilon_2 X^{a_\gamma + b_\delta} + \text{higher order terms},$$

and

$$[(f - f_*)(g - g_{**})](\omega) = \pm \varepsilon_1 \varepsilon_2 \omega^{a_\gamma + b_\delta} + h_3(\omega),$$

where $h_3(\omega) \ll \omega^{a_\gamma + b_\delta}$. So by cofinality,

$$f(\omega)g(\omega) = \{ (f \cdot g)(\omega) - \varepsilon \omega^{a_\gamma + b_\delta} : \gamma < \alpha, \delta < \beta, \varepsilon \in \mathbb{R}^{>0} \mid \\ (f \cdot g)(\omega) + \varepsilon \omega^{a_\gamma + b_\delta} : \gamma < \alpha, \delta < \beta, \varepsilon \in \mathbb{R}^{>0} \}.$$

Now,

$$(f \cdot g)(\omega) = \{(f \cdot g)(\omega) - \varepsilon \omega^{a_\gamma + b_\delta} : \gamma < \alpha, \delta < \beta \text{ s.t. } a_\alpha + b_\delta \in \text{supp}(f \cdot g), \varepsilon \in \mathbb{R}^{>0} \mid \\ f \cdot g(\omega) + \varepsilon \omega^{a_\gamma + b_\delta} : \gamma < \alpha, \delta < \beta \text{ s.t. } a_\alpha + b_\delta \in \text{supp}(f \cdot g), \varepsilon \in \mathbb{R}^{>0}\}.$$

Thus, $(f \cdot g)(\omega)$ satisfies the cut for $f(\omega) \cdot g(\omega)$ and the claim follows by cofinality. \square

All together, this completes the proof of the following theorem.

Theorem 6.10. *The map*

$$\mathbb{R}((t^{\mathbf{No}})) \xrightarrow{\sim} \mathbf{No}, \quad \sum_{i < \alpha} f_i X^{a_i} \mapsto \sum_{i < \alpha} f_i \omega^{a_i},$$

is an ordered field isomorphism.

7 The Surreals as a Real Closed Field

Let K be a field. We call K *orderable* if some ordering on K makes it an ordered field. If K is orderable, then $\text{char}(K) = 0$ and K is not algebraically closed.¹ We call K *euclidean* if $x^2 + y^2 \neq -1$ for all $x, y \in K$ and $K = \{\pm x^2 : x \in K\}$. If K is euclidean, then K is an ordered field for a unique ordering—namely, $a \geq 0 \iff \exists x \in K. x^2 = a$.

Theorem 7.1 (Artin & Schreier, 1927). *For a field K , the following are equivalent.*

- (1) *K is orderable, but has no proper orderable algebraic field extension.*
- (2) *K is euclidean and every polynomial $p \in K[X]$ of odd degree has a zero in K .*
- (3) *K is not algebraically closed, but $K(i)$, $i^2 = -1$, is algebraically closed.*
- (4) *K is not algebraically closed, but has an algebraically closed field extension L with $[L : K] < \infty$.*

*We call K real closed if it satisfies one of these equivalent conditions.*²

Corollary 7.2. Let K' be a subfield of a real closed field K . Then K' is real closed if and only if K' is algebraically closed in K .

Proof. Suppose K' is not algebraically closed in K . Fix $a \in K \setminus K'$ that is algebraic over K' . Then, $K'(a)$ is an proper orderable algebraic field extension of K' . Thus, K' is not real closed by (1) of theorem (7.1).

Conversely, suppose K' is algebraically closed in K . We verify that condition (2) of theorem (7.1) holds for K' . Since K' is algebraically closed in K , any zero of a polynomial of the form $X^2 - a$ or $-X^2 - a$, where $a \in K'$, must be in K' . This along with the fact that K is euclidean implies that K' is euclidean. Moreover, if $p \in K'[X]$ has odd degree, then since K satisfies (2), p has a zero $a \in K$. But, $a \in K'$ since K' is algebraically closed in K . Thus, K is real closed. \square

The archetypical example of a real closed field is \mathbb{R} . By corollary (7.2), the algebraic closure of \mathbb{Q} in \mathbb{R} is also real closed. In fact, the algebraic closure of \mathbb{Q} in \mathbb{R} can be embedded into any real closed field.

Proposition 7.3. Suppose K is real closed and $p \in K[X]$. Then,

- (1) *p is monic and irreducible if and only if $p = X - a$ for some $a \in K$ or $p = (X - a)^2 + b^2$ for some $a, b \in K$, $b \neq 0$.*

¹To prove that K is not algebraically closed: suppose K is an algebraically closed ordered field and derive a contradiction using i , the square root of -1 .

²See Lange's *Algebra* for partial proof.

(2) The map $x \mapsto p(x) : K \rightarrow K$ has the intermediate value theorem.

Theorem 7.4 (Tarski). *The theory of real closed ordered fields in the language $\mathcal{L} = \{0, 1, +, -, \cdot, \leq\}$ of ordered rings admits quantifier elimination. Hence, for any real closed field K , $\mathbb{R} \equiv K$ and, if \mathbb{R} is a subfield of K , then $\mathbb{R} \preceq K$.*

Theorem 7.5. *Let Γ be a divisible ordered abelian group and let k be a real closed field. Then, $K = k((t^\Gamma))$ is real closed.*

We have $K[i] \cong k[i]((t^\Gamma))$, so it's enough to show the following theorem.

Theorem 7.6. *Let Γ be a divisible ordered abelian group and let k be an algebraically closed field of characteristic 0. Then, $K = k((t^\Gamma))$ is algebraically closed.*

Remark. This theorem is still true if we drop the characteristic 0 assumption, but it would require a different proof than the one given below.

Proof. Let $P \in K[X]$ be monic and irreducible, and write

$$P = X^n + a_{n-1}X^{n-1} + \cdots + a_0 \quad (a_i \in K, n \geq 1).$$

By replacing $P(X)$ by $P(X - a_{n-1})$, we get

$$P\left(X - \frac{a_{n-1}}{n}\right) = X^n + \text{terms of degree} < n - 1.$$

Thus, we may assume $a_{n-1} = 0$. Put $\gamma_i := va_i \in \Gamma \cup \{\infty\}$ (recall that $vf := \min \text{supp } f$ for $f \in K$) and put

$$\gamma := \min \left\{ \frac{1}{n-i} \gamma_i : i = 0, \dots, n-2 \right\} \in \Gamma.$$

Then,

$$t^{-n\gamma} P(t^\gamma X) = X^n + \sum_{i=0}^{n-2} a_i t^{(i-n)\gamma} X^i,$$

where $v(a_i t^{(i-n)\gamma}) = \gamma_i + (i-n)\gamma \geq 0$, with equality holding for some i . Thus, we may assume $va_i \geq 0$ for all i , and $va_i = 0$ for some i .

Let $\mathcal{O} := \{f \in K : vf \geq 0\}$. It is readily verified that this is a subring of K which contains k . We have a ring morphism $\mathcal{O} \rightarrow k$ define by

$$f = \sum_{\gamma \geq 0} f_\gamma t^\gamma \mapsto f_0 =: \bar{f}.$$

Lemma 7.7. *Let $P \in \mathcal{O}[X]$ be monic and $\bar{P} = Q_0 R_0$, where $Q_0, R_0 \in k[X]$ are monic and relatively prime. Then there are monic $Q, R \in \mathcal{O}[X]$ with $P = QR$ and $\bar{Q} = Q_0, \bar{R} = R_0$.*

The lemma applies to our P . Since P is assumed irreducible, the lemma implies $\bar{P} = (X - a)^n$ for some $a \in k$, i.e.,

$$\bar{P} = X^n - naX^{n-1} + \text{lower degree terms}.$$

Since $a_{n-1} = 0$, we have $na = 0$; hence, $a = 0$ since k has characteristic 0. Thus, $\bar{P} = X^n$. But, $va_i = 0$ for some i , so we have a contradiction.

We now prove the lemma. Write $P = \sum_{i < \alpha} P_i(X) t^{a_i} \in k[X]((t^\Gamma))$, where a_i is strictly increasing in Γ , $a_0 = 0$, $P_i(X) \in k[X]$ are of degree $< n$ for $i > 0$, and $P_0 = \bar{P}$. Suppose we have a strictly increasing sequence $(b_i)_{i < \beta}$ in Γ and sequences $(Q_i)_{i < \beta}, (R_i)_{i < \beta}$ of polynomials in $k[X]$ of degree $< \deg Q_0$ and $< \deg R_0$, respectively, such that for

$$Q_{<\beta} := \sum_{i < \beta} Q_i t^{b_i}, \quad R_{<\beta} := \sum_{i < \beta} R_i t^{b_i}$$

we have

$$P \equiv Q_{<\beta} R_{<\beta} \pmod{(t^b \mathcal{O})}$$

for all $b \in \Gamma$ with $b \leq b_i$ for some i . Suppose $P \neq Q_{<\beta} R_{<\beta}$; we are going to find $b_\beta \in \Gamma$ and $Q_\beta, R_\beta \in k[X]$ of degrees $< \deg Q_0$ and $< \deg R_0$, respectively, such that

- $b_\beta > b_i$ for all $i < \beta$.
- $P \equiv (Q_{<\beta} + Q_\beta t^{b_\beta})(R_{<\beta} + R_\beta t^{b_\beta}) \pmod{(t^b \mathcal{O})}$ for all $b \leq b_\beta$.

To this end, let $\gamma := v(P - R_{<\beta} Q_{<\beta}) \in \Gamma$. Then, $b_\beta := \gamma > b_i$ for all $i < \beta$. Consider any $G, H \in k[X]$; then

$$P \equiv (Q_{<\beta} + Q_\beta t^{b_\beta})(R_{<\beta} + R_\beta t^{b_\beta}) \pmod{(t^b \mathcal{O})}$$

for all $b \leq b_\beta$. To get this congruence to hold also for $b = b_\beta$, we need G, H to satisfy an equation

$$S = Q_0 H + R_0 G,$$

where $S \in k[X]$ has degree < 0 . But we can find such G, H since Q_0, R_0 are relatively prime. Then, take $Q_\beta = G$ and $R_\beta = H$ for such G, H .

Week 8

November 24, 2014

Notes for today by Madeline Barnicle

Write $x \in \mathbf{No}$ in normal form. Say all powers of ω are positive. Take an initial segment of x ; the segment also has this property. The proof requires the **sign sequence** (chapter 5 of Gonshor), and we need this to delve into the exponential function. Instead, we will cover:

8 Analytic functions on No

Let Γ be an ordered abelian group, $K = \mathbb{R}((t^\Gamma))$, $x = t^{-1}$. Let $F : I \rightarrow \mathbb{R}$ ($I = (a, b)$, $a < b \in \mathbb{R} \cup \{\pm\infty\}$). Suppose F is analytic. Then F extends to a function $F_K : I_K \rightarrow K$, where $I_K = \{f \in K : a < f < b\}$. To explain this, consider the \mathbb{R} -subspaces:

$K^\downarrow = \{f \in K : \text{supp}(f) \subset \Gamma^{>0}\}$ (infinitesimals of K)

$K^\uparrow = \{f \in K : \text{supp}(f) \subset \Gamma^{<0}\}$ (the "purely infinite" elements of K)

So $K = K^\downarrow \oplus \mathbb{R} \oplus K^\uparrow$. $O = K^\downarrow \oplus \mathbb{R}$. Then $I_K = \{c + \epsilon \mid c \in I \subset \mathbb{R}, \epsilon \in K^\downarrow\}$. Set $F_K(c + \epsilon) = \sum_{n=0}^{\infty} \frac{F^{(n)}(c)}{n!} \epsilon^n \in K$, which converges in K by Neumann's lemma. For example, $c \rightarrow e^c : \mathbb{R} \rightarrow \mathbb{R}^{>0}$ extends this way to $c + \epsilon \rightarrow e^{c+\epsilon} = e^c \sum_{n=0}^{\infty} \frac{\epsilon^n}{n!}$, $O \rightarrow K^{>0}$.

Likewise, every analytic function $G : U \rightarrow \mathbb{R}$ where $U \subset \mathbb{R}^n$ is open extends to a K -valued function whose domain U_K is the set of all points in K^n of infinitesimal distance to a point in U .

Digression on exp for No

An **exponential function** on K is an isomorphism $(K, \leq, +) \rightarrow (K^{\geq 0}, \geq, \cdot)$.

A negative result:

Theorem 8.1 (F.-V. and S. Kuhlmann, Shelah). *If the underlying class of Γ is a set, and $\Gamma \neq \{0\}$, then there is **no** exponential function on $\mathbb{R}((t^\Gamma))$.*

Nevertheless, there is an exponential function on $\mathbf{No} \cong \mathbb{R}((t^{\mathbf{No}}))$ (Gonshor/Kruskal).

For the rest of the course we will focus on restricted analytic functions on \mathbf{No} .

Let $I = [-1, 1] \subset \mathbb{R}$. A restricted analytic function is a function $F : \mathbb{R}^m \rightarrow \mathbb{R}$ such that $F(x) = 0$ for $x \in \mathbb{R}^m \setminus I^m$, and $F|_{I^m}$ extends to an analytic function $U \rightarrow \mathbb{R}$ for some neighborhood U of I^m .

Example: $F : \mathbb{R} \rightarrow \mathbb{R}$ given by $F(x) = 0$ if $|x| > 1$, $F(x) = e^x$ if $|x| \leq 1$. For each such F , we have a function $F_K : K^M \rightarrow K$ such that $F_K(x) = 0$ if $x \in K^M \setminus I_K^M$, $F_K|_{I_K^M}$ extends to a function $G_K : U_K \rightarrow K$ where $G : U \rightarrow \mathbb{R}$ is an analytic extension of $F|_{I^m}$ to an open neighborhood U of I^m .

Example: for F as before, $F_K(x) = 0$ if $|x| > 1$. $F_K(c + \epsilon) = e^c \sum_{n=0}^{\infty} \frac{\epsilon^n}{n!}$, for $x = c + \epsilon$, $|x| \leq 1$.

Let L_{an} be the language $\{0, +, -, \cdot, \leq\}$ of ordered rings, augmented by a function symbol for each restricted analytic $\mathbb{R}^m \rightarrow \mathbb{R}$ (as m varies). Let $\mathbb{R}_{an} = \mathbb{R}$ with the natural L_{an} structure, $K_{an} = \mathbb{R}((t^\Gamma))$ with the natural structure (extensions as above). $\mathbb{R}_{an} \leq K_{an}$.

Theorem 8.2 (van den Dries, Macintyre, Marker, extending Denef-van den Dries). *If Γ is divisible, then $\mathbb{R}_{an} \prec K_{an}$ (elementary substructure). In particular, $\mathbb{R} \prec \mathbf{No}$.*

vd Dries and Ehrlich expanded this by adding the exponential function to both sides.

9 Power series and Weierstrass Preparation

Let A be a commutative ring with 1, $X = (x_1 \dots x_m)$ indeterminates. $A[[x]] = A[[x_1, \dots, x_m]] = \{f = \sum_{i \in \mathbb{N}^m} f_i x^i, f_i \in A\}$, **the ring of formal power series in X over A** . Here, $X^i = x_1^{i_1} \dots x_m^{i_m}$. These terms can be added or multiplied in the obvious way.

$A \subset A[x] \subset A[[x]]$. For $i = (i_1 \dots i_m) \in \mathbb{N}^m$, put $|i| = i_1 + \dots + i_m$. For $f \in A[[x]]$, $\text{order}(f) = \min\{|i| : f_i \neq 0\}$ if $f \neq 0$, or ∞ if $f = 0$.

$\text{ord}(f + g) \geq \min(\text{ord}(f), \text{ord}(g))$. $\text{ord}(fg) \geq \text{ord}(f) + \text{ord}(g)$, with equality if and only if A is an integral domain. $A[[x]]$ is an integral domain if and only if A is.

Let $(f_j)_{j \in J}$ be a family in $A[[x]]$. If for all $d \in \mathbb{N}$ there are only finitely many $j \in J$ with $\text{ord}(f_j) \leq d$, then we can make sense of $\sum_{j \in J} f_j \in A[[x]]$. We often write $f \in A[[x]]$ as $f = \sum_{d \in \mathbb{N}} f_d$ where $f_d = \sum_{|i|=d} f_i x^i$ is the degree- d homogeneous part of f .

November 26, 2014

Let A be a commutative ring, X a set of m indeterminates X_1, \dots, X_m . For $f = \sum f_i X^i \in A[[X]]$, the map $f : A[[X]] \rightarrow A$ given by $f \mapsto f_0$ (here 0 is the multi-index $(0, 0, \dots, 0)$) is a ring morphism sending f to its **constant term**.

Lemma 9.1. *Let $f \in A[[X]]$. Then f is a unit in $A[[X]]$ if and only f_0 is a unit in A .*

Proof. The “if” direction is clear. For the converse, suppose $f_0 g_0 = 1$, where $g_0 \in A$. Then $f g_0 = 1 - h$, where $\text{ord}(h) \geq 1$. Now we can apply the usual geometric series trick: take $\sum_n h^n \in A[[X]]$, which is defined using the notion of infinite sum defined last time, and check that $g_0 \cdot \sum_n h^n$ is an inverse for f . \square

Define $\mathfrak{o} = \{f \in A[[X]] : \text{ord}(f) \geq 1\} = \{f : f_0 = 0\}$. This is an ideal of $A[[X]]$, and $A[[X]] = A \oplus \mathfrak{o}$ as additive groups.

Every $f \in \mathfrak{o}$ is of the form $f = x_1 g_1 + \dots + x_m g_m$, where $g_i \in A[[X]]$ (of course, this representation is not unique). More generally, set $\mathfrak{o}^d :=$ the ideal of $A[[X]]$ generated by products f_1, \dots, f_d with $f_i \in \mathfrak{o}$. Equivalently, this is the ideal $\{f : \text{ord}(f) \geq d\}$ or the ideal generated by monomials of the form X^i , where $|i| = d$. That these are indeed equivalent is a straightforward exercise.

We will also need to define **substitution**. Let $Y = (y_1, \dots, y_n)$ be another tuple of distinct indeterminates, and let $g_1, \dots, g_m \in A[[Y]]$ with constant term 0. Define a ring morphism $A[[X]] \rightarrow A[[Y]]$ by $f \mapsto f(g_1, \dots, g_m) = \sum_i f_i g^i$. In the usual applications of this definition, we’ll have $X = Y$.

Let’s introduce some more basic definitions for working with several sets of indeterminates. Suppose that X and Y are sets of indeterminates $\{X_1, \dots, X_m\}$ and $\{Y_1, \dots, Y_n\}$ respectively, and that none of the indeterminates in Y appears in X . Put $(X, Y) := (X_1, \dots, X_m, Y_1, \dots, Y_n)$. Then for $f \in A[[X, Y]]$, we can write

$$f = \sum_{i,j} f_{ij} X^i Y^j.$$

This can be rewritten as $\sum_j (\sum_i f_{ij} X^i) Y^j$ (the sums above are actually the infinite sums defined last time). This gives an identification of $A[[X, Y]]$ with $A[[X]][[Y]]$.

The previous result can be sharpened somewhat.

Lemma 9.2. *Let $f \in A[[X, Y]]$. Then there are unique $g_1, \dots, g_n \in A[[X, Y]]$ such that*

$$f(X, Y) = f(X) + X_1 g_1(X, Y_1) + \dots + Y_n g_n(X, Y_1, \dots, Y_n)$$

where $g_i \in A[[X, Y_1, \dots, Y_i]]$.

The proof is an exercise.

From now on, we will take A to be a field K . Let T be an indeterminate not among X_1, \dots, X_m . We call $f(X, T) \in A[[X, T]]$ **regular in T of order d** if

$$f(0, T) = cT^d + \text{terms of order larger than } d$$

where $c \in K - \{0\}$.

Writing $f = \sum_{i \in \mathbb{N}} f_i(X) T^i$, this is also equivalent to either of the following:

1. $f_0(0) = \dots = f_{d-1}(0) = 0$ and $f_d(0) \neq 0$,
2. $f_0, \dots, f_{d-1} \in \mathfrak{o}$, $f_d \in \mathfrak{o}$, $f_d \in K[[X]]^\times$.

The reason for this definition is that there is a "Euclidean division" result which holds when dividing by regular power series.

Theorem 9.3 (Division with remainder). *Let $f \in K[[X, T]]$ be regular in T of order d . Then for each $g \in K[[X, T]]$, there is a unique pair (Q, R) where $Q \in K[[X, T]]$ and $R \in K[[X]][T]$ (so it is just a polynomial in T) such that $g = Qf + R$ and $\deg_T R < d$.*

Proof. We first reduce to the case $f = T^d + F$, where $F \in \mathfrak{o}[[T]]$. Here $\mathfrak{o}[[T]]$ is a notation for the set of power series in T whose coefficients are in \mathfrak{o} . Write $f = \sum_i f_i(X)T^i$, where $f_0, \dots, f_{d-1} \in \mathfrak{o}$, $f_d \in K[[X]]^\times$. Then set $u := \sum_{i \geq d} f_i T^{i-d}$. Then $u^{-1}f = u^{-1}(\sum_{i < d} f_i(X)T^i) + T^d \in \mathfrak{o}[[T]] + T^d$.

Now we prove uniqueness: if $g = Q_1 f + R_1 = Q_2 f + R_2$ are both as in the conclusion of the theorem, then $qf = r$ where $q := Q_1 - Q_2$ and $r := R_2 - R_1$, so and $\deg_T R < d$. Suppose $q = \sum_i q_i T^i$. For each i , the coefficient of T^{d+i} in qf is 0 (since $qf = r$ has degree $< d$), which can be expressed as $0 = q_i f_d + \sum_{j < i} q_j f_{d+i-j} + \sum_{i < j \leq i+d} q_j f_{d+i-j}$. Thus $q_i \in \mathfrak{o}$ for each i . Repeating this inductively, we see that each q_i must be in \mathfrak{o}^n for each $n \in \mathbb{N}$, so they must all be 0. Hence $q = 0$, and then $r = 0$.

Finally we show existence, the more interesting part of the proof. Define $K[[X]]$ -linear maps $\tau, \lambda : K[[X, T]] \rightarrow K[[X, T]]$ and $\alpha : K[[X, T]] \rightarrow K[[X]][T]$ by

1. $\tau(g) := \sum_i g_{i+d} T^i$ (the higher order part of g , divided out by T^d),
2. $\lambda(g) := -\tau(g)F$ (recalling that $F = f - T^d$ was the $\mathfrak{o}[[T]]$ part of f)
3. $\alpha(g) := g_0 + g_1 T + \dots + g_{d-1} T^{d-1}$ (the lower degree terms of g).

Notice that $g = \tau(g)T^d + \alpha(g) = \tau(g)f + \alpha(g) + \lambda(g)$. Informally, $\tau(g)$ is our first guess for the quotient part. Then $\alpha(g)$ collects the lower degree terms of the remainder, and $\lambda(g)$ is an extra part that we must work to refine.

We will do this by iterating the process above. For each n , applying the process above to $\lambda^n(g)$ we have $\lambda^n(g) = \tau(\lambda^n(g))f + \alpha(\lambda^n(g)) + \lambda^{n+1}(g)$. (Let us denote this equation by $(*)_n$). If $g \in \mathfrak{o}^n[[T]]$, then $\tau(g), \alpha(g) \in \mathfrak{o}^n[[T]]$, and $\lambda(g) \in \mathfrak{o}^{n+1}[[T]]$, so the order always increases after applying λ (this is a sign that we make some progress after applying λ).

Using $(*)_n$ to iterate the λ away, we see that:

$$\begin{aligned} g &= \tau(g)f + \alpha(g) + \lambda(g) \\ &= \tau(g)f + \alpha(g) + \tau(\lambda(g))f + \alpha(\lambda(g)) + \lambda^2(g) \\ &= \sum_n \tau(\lambda^n(g))f + \sum_n \alpha(\lambda^n(g)). \end{aligned}$$

We can take $Q := \sum_n \tau(\lambda^n(g))$ and $R := \sum_n \alpha(\lambda^n(g))$. These sums are defined since $\tau(\lambda^n(g))$ and $\alpha(\lambda^n(g))$ have order n . \square

Week 9

Monday 12-1-2014

(Notes today by John Lensmire.)

Corollary 9.4 (Weierstrass Preparation). Let $f \in K[[X, T]]$ be regular of order d in T . Then $f \in K[[X, T]]^\times$ and $W \in K[[X]][T]$ is monic of degree d in T .

Proof. Using Theorem 9.3, we can write $T^d = Qf + R$ where $Q \in K[[X, T]]$, $R \in K[[X]][T]$, $\deg_T R < d$.
Let $x = 0$ to get

$$T^d = \left(\sum_i Q_i(0)T^i \right) (f_d(0) + \text{terms of higher order}) + R_0(0) + R_1(0)T + \cdots + R_{d-1}(0)T^{d-1}.$$

Looking at the coefficient of T^d , we have $1 = Q_0(0)f_d(0)$. This implies $Q_0 \in K[[X]]^\times$ and thus $Q \in K[[X, T]]^\times$.

Hence, we have $f = uW$ where $u = Q^{-1}$ and $W = T^d - R$.

Uniqueness follows from the uniqueness in Theorem 9.3 (details are left as an exercise.) □

Remark. The above proof shows that we can take W to be a Weierstrass polynomial, i.e. a monic polynomial $W = T^d + W_{d-1}T^{d-1} + \cdots + W_0$ where $W_0, \dots, W_{d-1} \in \mathfrak{o}[[X]]$.

Corollary 9.5. Suppose K is infinite. Then the ring $K[[X]]$ is noetherian.

Proof. We proceed by induction on m .

If $m = 0$, K is a field, hence noetherian.

From m to $m + 1$: Let $\{0\} \neq I \subset K[[X, T]]$ be an ideal. Take $f \in I \setminus \{0\}$, after replacing I, f by images under a suitable automorphism of $K[[X, T]]$ (see last time) we can assume that f is regular in T of some order d . Then each $g \in I$ can be written as $g = qf + r$, where $q \in K[[X, T]]$ and $r \in A[T]$ is of degree $< d$ ($A = K[[X]]$). Hence, $r \in I \cap (A + AT + \cdots + AT^{d-1})$. By induction $J := I \cap (A + AT + \cdots + AT^{d-1})$ is a finitely generated A -module.

Therefore, I is generated by f and the (finitely many) generators of J , as needed. □

10 Convergent Power Series

A *polyradius* is a vector $r = (r_1, \dots, r_m) \in (R^{\geq 0})^m$. Given polyradii r, s we write

1. $r \leq s \Leftrightarrow r_i \leq s_i$ for each i .
2. $r < s \Leftrightarrow r_i < s_i$ for each i .
3. $r^i = r_1^{i_1} \cdots r_m^{i_m}$ for $i = (i_1, \dots, i_m) \in \mathbb{N}^m$.

Given a polyradius r and $a \in \mathbb{C}^m$, $D_r(a) := \{x \in \mathbb{C}^m \mid |x_i - a_i| < r_i \text{ for } i = 1, \dots, m\}$, called the *open polydisk* centered at a with polyradius r . Its closure, $\overline{D_r(a)}$, is the *closed polydisk* centered at a with polyradius r .

For $f \in \mathbb{C}[[X]]$, define $\|f\|_r := \sum_i |f_i| r^i \in \mathbb{R}^{\leq 0} \cup \{+\infty\}$. Writing $\|\cdot\| = \|\cdot\|_r$, it is easy to verify:

1. $\|f\| = 0 \Leftrightarrow f = 0$.
2. $\|cf\| = |c| \cdot \|f\|$ for $c \in \mathbb{C}$.
3. $\|f + g\| \leq \|f\| + \|g\|$.
4. $\|f \cdot g\| \leq \|f\| \cdot \|g\|$.

$$5. \|X^i f\| = r^i \|f\|.$$

$$6. r \leq s \Rightarrow \|f\|_r \leq \|f\|_s.$$

Definition 10.1. $\mathbb{C}\{X\}_r := \{f \in \mathbb{C}[[X]] \mid \|f\|_r < +\infty\}$

Lemma 10.2. 1. $\mathbb{C}\{X\}_r$ is a subalgebra of $\mathbb{C}[[X]]$ containing $\mathbb{C}[X]$.

2. $\mathbb{C}\{X\}_r$ is complete with respect to the norm $\|\cdot\|_r$.

Proof. 1. is clear. 2. is routine using a "Cauchy Estimate": for every $i \in \mathbb{N}^m$, $|f_i| \leq \|f\|_r / r^i$, and is left as an exercise. \square

Each $f \in \mathbb{C}\{X\}_r$ gives rise to a function $\overline{D_r}(0) \rightarrow \mathbb{C}$ as follows: For $x \in \overline{D_r}(0)$, the series $\sum_i f_i x^i$ converges absolutely to a complex number $f(x)$. This function $x \mapsto f(x)$ is continuous (as it is the limit of uniformly continuous functions).

For $f \in \mathbb{C}[[X, Y]]$, $f = \sum_{j \in \mathbb{N}^n} f_j(X) Y^j$, and $(r, s) \in (\mathbb{R}^{\geq 0})^{m+n}$ a polyradius, we have (from the definitions) $\|f\|_{(r,s)} = \sum_j \|f_j\|_r s^j$. Hence, $f \in \mathbb{C}\{X, Y\}_{(r,s)}$ and in particular $f_j \in \mathbb{C}\{X\}_r$ for all j . Further, we have, for $x \in \overline{D_r}(0)$, $f(x, y) := \sum_j f_j(X) Y^j \in \mathbb{C}\{Y\}_s$, and for $(x, y) \in \overline{D_{(r,s)}}(0)$, $f(x, y) = \left(\sum_j f_j(X) Y^j \right)(y) = \sum_j f_j(x) y^j$.

Lemma 10.3. The map that sends $f \in \mathbb{C}\{X\}_r$ to f_r given by $x \mapsto f(x)$ is an injective ring morphism:

$$\mathbb{C}\{X\}_r \rightarrow \{ \text{ring of continuous functions } \overline{D_r}(0) \rightarrow \mathbb{C} \}$$

Further, $\|f_r\|_{\sup} \leq \|f\|_r$.

Proof. All claims follow from definitions directly except injectivity. By induction on m , we show: $f \in \mathbb{C}\{X\}_r \setminus \{0\}$ implies f_r does not vanish identically on any open neighborhood of $0 \in \mathbb{C}^m$.

If $m = 1$, write $f = X^d(f_d + f_{d+1}X + \dots)$, where $f_i \in \mathbb{C}$, $f_d \neq 0$.

For $|x| \leq r$, the series $f_d + f_{d+1}X + \dots$ converges to a continuous function of X . This function takes value $f_d \neq 0$ at $x = 0$, hence is non-zero in a neighborhood around 0.

For $m \geq 2$, write $f = \sum_i f_i(X') X_m^i$, where $X' = (X_1, \dots, X_{m-1})$, $f_i \in \mathbb{C}\{X'\}_{r'}$ with $r' = (r_1, \dots, r_{m-1})$. Then $\|f\|_r = \sum_i \|f_i\|_{r'} r_m^i$ and $f(x) = \sum_i f_i(X') X_m^i$ for $X = (X', X_m) \in \overline{D_r}(0)$. Fix j such that $f_j(X') \neq 0$. By the induction hypothesis, there are $X' \in \mathbb{C}^{m-1}$ as close as we want to 0 such that $f_j(X') \neq 0$. For such an X' (as in the $m = 1$ case), we have $f(X', X_m) \neq 0$ for all sufficiently small X_m . \square

11 Siddharth's extra lectures

Part 1

notes by Bill Chen

A crucial concept for these lectures will be **games**. These games where two players Left and Right alternate moves, and a player loses if she has no moves. The information of who goes first is not encoded into the game. Formally, a game G consists of two sets of games, $G = \{G_L | G_R\}$, where the left side consists of the valid games which Left can move to, and similarly for the right side. (We use the "typical element" notation for sets, which carries over from the notation for surreal numbers.)

- Example 11.1.**
1. $\{\emptyset | \emptyset\}$ is called the zero game (abbreviated 0). There are no legal moves for either player, and the first player to move loses.
 2. $\{\emptyset | 0\}$ is the game 1. In this game, Left has no legal moves, and Right can move to the 0 game, so Right has a winning strategy no matter who moves first.
 3. $\{0 | \emptyset\}$. Here Left has a winning strategy.
 4. $\{0 | 0\}$ First player to move wins. This is a valid game which is not a surreal number as we defined in Week 2.

- Definition 11.2.**
1. $G > 0$ if Left has a winning strategy.
 2. $G < 0$ if Right has a winning strategy.
 3. $G \sim 0$ if the second player has a winning strategy. (G is "similar" to 0.)
 4. $G \parallel 0$ if the first player has a winning strategy. (G is "fuzzy".)
 5. $G \geq 0$ means $G > 0$ or $G \sim 0$.

Lemma 11.3. For any game G , one of $G > 0$, $G < 0$, $G \sim 0$, or $G \parallel 0$ holds.

Proof. Let A be the assertion that there is a G_L with $G_L \geq 0$, and B be the assertion that there is a G_R with $G_R \leq 0$.

Then one can check that $G > 0$ iff $A \& \neg B$, $G < 0$ iff $\neg A \& B$, $G \sim 0$ iff $\neg A \& \neg B$, and $G \parallel 0$ iff $A \& B$. For example, if $A \& B$ holds, then the first player can move to a game that is positive or similar 0. In the first case, the first player clearly wins. In the second case, the first player becomes the second player of the new game similar to 0, and hence wins. \square

Definition 11.4.

If G, H are games, the **disjunctive sum** $G + H$ is the game in which G and H are "played in parallel." Formally,

$$G + H = \{G_L + H, G + H_L | G_R + H, G + H_R\}.$$

Remark. By induction, can prove that $+$ is associative and commutative.

Definition 11.5. If G is a game, the **negation** $-G$ is the game obtained by switching the roles of Left and Right. Formally,

$$-G = \{-G_R | -G_L\}.$$

Notice that these are the same definitions as for surreal numbers.

Lemma 11.6.

1. $-(G + H) = -G + -H$.

2. $--G = G$.

3. $G \sim 0$ iff $-G \sim 0$.
4. $G > 0$ iff $-G < 0$.
5. $G \parallel 0$ iff $-G \parallel 0$.

We won't prove this lemma, but it is not difficult.

Lemma 11.7. *Let $H \sim 0$. Then:*

1. *If $G \sim 0$, then $G + H \sim 0$.*
2. *If $G > 0$, then $G + H > 0$.*
3. *If $G \parallel 0$, then $G + H \parallel 0$.*
4. *If $G + H \sim 0$, then $G \sim 0$.*
5. *If $G + H > 0$, then $G > 0$.*
6. *If $G + H \parallel 0$, then $G \parallel 0$.*

Proof. Formally, this is proved by induction. We just describe the strategies in words.

For (1), if the second player has a winning strategy in G and H , then the second player can use the winning strategy corresponding to the game in which the first player plays in.

For (2), the proof splits into cases. If Right moves first, either Right moves in H , so Left can play according to the second player's strategy in the H game, or Right moves in G , so Left can play according to his strategy in G . If Left moves first, he plays according to his strategy in G and then according to the previous sentence against the subsequent moves of Right.

(3), is a similar analysis. □

The next three follow from the first three by using cases based on determinacy.

Lemma 11.8. 1. $G + -G \sim 0$.

2. *If $G > 0$ and $H > 0$ then $G + H > 0$.*

Proof. The first assertion follows from the strategy of "playing Go on two boards against the same person." □

Definition 11.9.

Definition 11.10.

$$G \sim H \iff G - H = 0.$$

$$G > H \iff G - H > 0.$$

Lemma 11.11. \sim is an equivalence relation.

Proof. 1.

$$G - H \sim 0 \iff -(G - H) \sim 0 \iff -G + H \sim 0 \iff H - G \sim 0,$$

$$\text{so } G \sim H \iff H \sim G.$$

2. $G \sim G$ because $G - G \sim 0$.

3. If $G \sim G'$ and $G' \sim H$ then $G \sim H$:

$$G \sim G' \sim 0 \text{ and } G' - H \sim 0 \Rightarrow G - G' + G' - H \sim 0 \Rightarrow G - H \sim 0.$$

□

Lemma 11.12. $<$ is an order (i.e. a transitive antisymmetric relation).

Proof. Similar to previous lemma. □

We want to show that the class of games modulo \sim forms a partially ordered abelian group with identity 0 (the \sim -class of $\{\emptyset|\emptyset\}$). That is, we want to show that if $G \sim G'$ and $H \sim H'$ then

- $G + H \sim G' + H'$
- $-G \sim -G'$
- $G > H \iff G' > H'$.

Theorem 11.13. **No** forms an ordered abelian subgroup of the partially ordered abelian group G of games.

Proof. We define a map $\pi: \mathbf{No} \rightarrow G$ and prove that it's an injective group homomorphism:

$$\pi: 0 \mapsto 0$$

$$\pi: \{L|R\} \mapsto \{\pi(L)|\pi(R)\}$$

We leave it as an exercise to verify that π is well-defined.

It's clear from the definitions of $+$ for surreal numbers and games that π is morphism of abelian groups.

We claim that $a = 0 \iff \pi(a) = 0$ and $a < b \iff \pi(a) < \pi(b)$. The proof is by induction on a .

Suppose that $\pi(a) = 0$, so $\{\pi(a_L)|\pi(a_R)\} = 0$. So $\pi(a_L) < 0 < \pi(a_R)$ for all a_L and a_R , and by induction $a_L < 0 < a_R$. So $a = \{a_L|a_R\} = 0$.

Suppose $\pi(a) < \pi(b)$, i.e., $\pi(b) - \pi(a) > 0$. Recall

$$\pi(a) - \pi(b) = \{\pi(b)_L - \pi(a), \pi(b) - \pi(a)_L \mid \pi(b)_R - \pi(a), \pi(b) - \pi(a)_R\},$$

using $\pi(b)_L = \pi(b_L)$.

$$\pi(a) - \pi(b) = \{\pi(b_L - a), \pi(b - a_R) \mid \pi(b_R - a), \pi(b - a_L)\} > 0.$$

For all b_R, a_L , $b_R - a > 0$ and $b - a_L > 0$. Since $a_L < b$ and $a < b_R$, we conclude that $a < b$. □
