Abstract. Aschenbrenner et. al. computed a bound $\mathrm{vc}(n) \leq 2n-1$ for the VC density function in the field of p-adic numbers, but it is not known to be optimal. I investigate a certain P-minimal additive reduct of the field of p-adic numbers and use a cell decomposition result of Leenknegt to compute an optimal bound $\mathrm{vc}(n) = n$ for that structure.

VC density was introduced into model theory in [1] by Aschenbrenner, Dolich, Haskell, MacPherson, and Starchenko as a natural notion of dimension for definable families of sets in NIP theories. In a NIP theory T we can define the vc-function

$$\mathrm{vc}_T = \mathrm{vc} : \mathbb{N} \longrightarrow \mathbb{N}$$

where $\mathrm{vc}(n)$ measures the worst-case complexity of families of definable sets in an n-dimensional space. The simplest possible behavior is $\mathrm{vc}(n) = n$ for all n. For $T = \mathrm{Th}(\mathbb{Q}_p)$, the paper [1] computes an upper bound for this function to be $2n-1$, and it is not known whether it is optimal. This same bound would hold in any reduct of the field of p-adic numbers, so one may expect that the simplified structure of the reduct would allow a better bound. In [2], Leenknegt provides a cell decomposition result for a certain P-minimal additive reduct of the field p-adic numbers. Using this result, in this paper we improve the bound for the VC function, showing that in Leenknegt's structure $\mathrm{vc}(n) = n$.

Explain organization of this paper, notation

1. VC-dimension and VC-density

Definition 1.1. Throughout this section we work with a collection $\mathcal{F}$ of subsets of a set X. We call the pair $(X, \mathcal{F})$ a set system.

- Given a subset A of X, we define the set system $(A, A \cap \mathcal{F})$ where $A \cap \mathcal{F} = \{A \cap F\}_{F \in \mathcal{F}}$.

- For $A \subset X$ we say that $\mathcal{F}$ shatters A if $A \cap \mathcal{F} = \mathcal{P}(A)$.

Definition 1.2. We say $(X, \mathcal{F})$ has VC-dimension n if the largest subset of X shattered by $\mathcal{F}$ is of size n. If $\mathcal{F}$ shatters arbitrarily large subsets of X, we say that $(x, \mathcal{F})$ has infinite VC-dimension. We denote the VC-dimension of $(X, \mathcal{F})$ by $\mathrm{VC}(\mathcal{F})$.

Note 1.3. We may drop X from the previous definition, as it VC-dimension doesn't depend on the base set and is determined by $(\bigcup \mathcal{F}, \mathcal{F})$.

This allows us to distinguish between well behaved set systems of finite VC-dimension which tend to have good combinatorial properties and poorly behaved set systems with infinite VC dimension.

Another natural combinatorial notion is that of a dual system:

Definition 1.4. For $a \in X$ define $X_a = \{F \in \mathcal{F} \mid a \in F\}$. Let $\mathcal{F}^* = \{X_a\}_{a \in X}$. We define $(\mathcal{F}, \mathcal{F}^*)$ as the dual system of $(X, \mathcal{F})$. The VC-dimension of the dual system of $(X, \mathcal{F})$ is referred to as the dual VC-dimension of $(X, \mathcal{F})$ and denoted by $\mathrm{VC}^*(\mathcal{F})$. (As before, this notion doesn't depend on X.)

Lemma 1.5. *A set system has finite VC-dimension if and only if its dual system has finite VC-dimension. More precisely*

$$\mathrm{VC}^*(\mathcal{F}) \leq 2^{1+\mathrm{VC}(\mathcal{F})}.$$

For a more refined notion we look at the traces of our family on finite sets:

Definition 1.6. Define the shatter function $\pi_{\mathcal{F}} \colon \mathbb{N} \longrightarrow \mathbb{N}$ and the dual shatter function $\pi^*_{\mathcal{F}} \colon \mathbb{N} \longrightarrow \mathbb{N}$ of $\mathcal{F}$ by

$$\pi_{\mathcal{F}}(n) = \max \{|A \cap \mathcal{F}| \mid A \subset X \text{ and } |A| = n\}$$

$$\pi^*_{\mathcal{F}}(n) = \max \{\text{number of atoms in Boolean algebra generated by } B \mid B \subset \mathcal{F}, |B| = n\}$$

Note that the dual shatter function is precisely the shatter function of the dual system: $\pi^*_{\mathcal{F}} = \pi_{\mathcal{F}^*}$

A simple upper bound is $\pi_{\mathcal{F}}(n) \leq 2^n$ (same for the dual). If VC-dimension is infinite then clearly $\pi_{\mathcal{F}}(n) = 2^n$ for all n. Conversely we have the following remarkable fact:

Theorem 1.7 (Sauer-Shelah '72)**.** *If the set system $(X, \mathcal{F})$ has finite VC-dimension d then $\pi_{\mathcal{F}}(n) \leq \binom{n}{\leq d}$ where $\binom{n}{\leq d} = \binom{n}{d} + \binom{n}{d-1} + \ldots + \binom{n}{1}$.*

Thus the systems with a finite VC-dimension are precisely the systems where the shatter function grows polynomially. Define VC-density to be the degree of that polynomial:

Definition 1.8. Define vc-density and dual vc-density of $\mathcal{F}$ as

$$\mathrm{vc}(\mathcal{F}) = \limsup_{n\to\infty} \frac{\log \pi_{\mathcal{F}}(n)}{\log n} \in \mathbb{R}^{\geq 0} \cup \{+\infty\}$$
$$\mathrm{vc}^*(\mathcal{F}) = \limsup_{n\to\infty} \frac{\log \pi^*_{\mathcal{F}}(n)}{\log n} \in \mathbb{R}^{\geq 0} \cup \{+\infty\}$$

Generally speaking a shatter function that is bounded by a polynomial doesn't itself have to be a polynomial. Proposition 4.12 in [1] gives an example of a shatter function that grows like $n \log n$ (so it has VC-density 1).

So far the notions that we have defined are purely combinatorial. We now adapt VC-dimension and VC-density to the model theoretic context.

Definition 1.9. Work in a structure M. Fix a finite collection of formulas $\Phi(x, y) = \{\phi_i(x, y)\}$.

- For $\phi(x, y) \in \mathcal{L}(M)$ and $b \in M^{|y|}$ let $\phi(M^{|x|}, b) = \{a \in M^{|x|} \mid \phi(a, b)\} \subseteq M^{|x|}$.
- Let $\Phi(M^{|x|}, M^{|y|}) = \{\phi_i(M^{|x|}, b) \mid \phi_i \in \Phi, b \in M^{|y|}\} \subseteq \mathcal{P}(M^{|x|})$.
- Let $\mathcal{F}_\Phi = \Phi(M^{|x|}, M^{|y|})$ giving a set system $(M^{|x|}, \mathcal{F}_\Phi)$.
- Define VC-dimension of Φ, $\mathrm{VC}(\Phi)$ to be the dual VC-dimension of $(M^{|x|}, \mathcal{F}_\Phi)$.
- Define VC-density of Φ, $\mathrm{vc}(\Phi)$ to be the dual VC-density of $(M^{|x|}, \mathcal{F}_\Phi)$.

We will also refer to the VC-density and VC-dimension of a single formula ϕ viewing it as a one element collection $\{\phi\}$.

Counting atoms of a Boolean algebra in a model theoretic setting corresponds to counting types, so it is instructive to rewrite the shatter function in terms of types.

Definition 1.10.

$$\pi_\Phi(n) = \max\{\text{number of } \Phi\text{-types over } B \mid B \subset M, |B| = n\}$$

$$\mathrm{vc}(\Phi) = \text{degree of polynomial growth of } \pi_\Phi(n) = \limsup_{n\to\infty} \frac{\log \pi_\Phi(n)}{\log n}$$

One can check that the shatter function and hence VC-dimension and VC-density of a formula are elementary notions, so they only depend on the first-order theory of the structure.

NIP theories are a natural context for studying VC-density. In fact we can take the following as the definition of NIP:

Definition 1.11. Define ϕ to be NIP if it has finite VC-dimension.

[**?**] shows that in a general combinatorial context, VC-density can be any real number in $0 \cup [1, \infty)$. Less is known if we restrict our attention to NIP theories. Proposition 4.6 in [1] gives examples of formulas that have non-integer rational VC-density in an NIP theory, however it is open whether one can get an irrational VC-density in this context.

In general, instead of working with a theory formula by formula, we can look for a uniform bound for all formulas:

Definition 1.12. For a given NIP structure M, define the <u>vc-function</u>

$$\mathrm{vc}^M(n) = \sup\{\mathrm{vc}(\phi(x, y)) \mid \phi \in \mathcal{L}(M), |x| = n\}$$

As before this definition is elementary, so it only depends on the theory of M. We omit the superscript M if it is understood from the context. One can easily check the following bounds:

Lemma 1.13 (Lemma 3.22 in [1])**.**

$$\mathrm{vc}(1) \geq 1$$

$$\mathrm{vc}(n) \geq n\,\mathrm{vc}(1)$$

However, it is not known whether the second inequality can be strict or even whether $\mathrm{vc}(1) < \infty$ implies $\mathrm{vc}(n) < \infty$.

2. P-adic numbers

The field of p-adic numbers is often studied in the language of Macintyre $\mathcal{L}_{Mac} = \{0, 1, +, -, \cdot, |, P_n\}$. which is a language of fields together with unary predicates $\{P_n\}_{n\in\mathbb{N}}$ interpreted in $\mathbb{Q}_p$ by

$$P_n x \leftrightarrow \exists y\ y^n = x$$

and a divisibility relation where $a|b$ holds when $\operatorname{val} a \leq \operatorname{val} b$.

Note that $P_n \setminus \{0\}$ is a multiplicative subgroup of $\mathbb{Q}_p$ with finitely many cosets.

Theorem 2.1 (Macintyre '76)**.** *The $\mathcal{L}_{Mac}$-structure $\mathbb{Q}_p$ has quantifier elimination.*

There is also a cell decomposition result.

Definition 2.2. Define <u>n-cell</u> recursively. 0-cells are points in $\mathbb{Q}_p$. An $n+1$-cell is a subset of $\mathbb{Q}_p^{n+1}$ of the following form:

$$\{(x,t) \in \mathbb{Q}_p \times D \mid \operatorname{val} a_1(x) \,\square_1\, \operatorname{val}(t - c(x)) \,\square_2\, \operatorname{val} a_2(x), t - c(x) \in \lambda P_n\}$$

where D is an n-cell, $a_1(x), a_2(x), c(x)$ are $\emptyset$-definable, $\square$ is $<, \leq$ or no condition, and $\lambda \in \mathbb{Q}_p$.

Theorem 2.3 (Denef '84)**.** *Any subset of $\mathbb{Q}_p$ defined by a $\mathcal{L}_{Mac}$-formula $\phi(x,t)$ with $|t| = 1$ and $|x| = n$ decomposes into a finite union of $n+1$-cells.*

In [1], Aschenbrenner, Dolich, Haskell, Macpherson, and Starchenko show that this structure has $\mathrm{vc}(n) \leq 2n-1$, however it is not known whether this bound is optimal.

In [2], Leenknegt analyzes the reduct of p-adic numbers to the language

$$\mathcal{L}_{aff} = \left\{ 0, 1, +, -, \{\bar{c}\}_{c \in \mathbb{Q}_p}, |, \{Q_{m,n}\}_{m,n \in \mathbb{N}} \right\}$$

where $\bar{c}$ is a scalar multiplication by c, $a|b$ stands for $\operatorname{val} a \leq \operatorname{val} b$, and $Q_{m,n}$ is a unary predicate

$$Q_{m,n} = \bigcup_{k \in \mathbb{Z}} p^{km}(1 + p^n \mathbb{Z}_p).$$

Note that $Q_{m,n}$ is a subgroup of the multiplicative group of $\mathbb{Q}_p$ with finitely many cosets. One can check that the extra relation symbols are definable in the $\mathcal{L}_{Mac}$-structure $\mathbb{Q}_p$. The paper [2] provides a cell decomposition result with the following cells:

Definition 2.4. A 0-cell is a point in $\mathbb{Q}_p$. An $n+1$-cell is a subset of $\mathbb{Q}_p^{n+1}$ of the following form:

$$\{(x,t) \in K \times D \mid \operatorname{val} a_1(x) \,\square_1\, \operatorname{val}(t - c(x)) \,\square_2\, \operatorname{val} a_2(x), t - c(x) \in \lambda Q_{m,n}\}$$

where D is an n-cell called the <u>base</u> of the cell, $a_1(x), a_2(x), c(x)$ are linear polynomials, $\square$ is $<$ or no condition, and $\lambda \in \mathbb{Q}_p$.

Theorem 2.5 (Leenknegt '12)**.** *Any formula $\phi(x,t)$ in $(\mathbb{Q}_p, \mathcal{L}_{aff})$ with $|t| = 1$ and $|x| = n$ decomposes into a union of $n+1$-cells.*

Moreover, [2] shows that $(\mathbb{Q}_p, \mathcal{L}_{aff})$ is a P-minimal reduct, that is the one-dimensional definable sets of $(\mathbb{Q}_p, \mathcal{L}_{aff})$ coincide with the one-dimensional definable sets in the full structure $(\mathbb{Q}_p, \mathcal{L}_{Mac})$.

I am able to compute the vc-function for this structure

Theorem 2.6. *Theorem (B.)* $(\mathbb{Q}_p, \mathcal{L}_{aff})$ *has* $\mathrm{vc}(n) = n$.

3. Key Lemmas and Definitions

Quantifier elimination result can be easily obtained from cell decomposition:

Lemma 3.1. *Any formula $\phi(x;y)$ in $(\mathbb{Q}_p, \mathcal{L}_{aff})$ can be written as a boolean combination of formulas from the following collection*

$$\Psi(x;y) = \{\mathrm{val}(p_i(x) - c_i(y)) < \mathrm{val}(p_j(x) - c_j(y))\}_{i,j \in I} \cup$$
$$\{p_i(x) - c_i(y) \in \lambda_k Q_{m,n}\}_{i \in I, k \in K}$$

where I, K are finite index sets, each p_i is a linear polynomial in x without a constant term, each c_i is a linear polynomial in y, and $\lambda_k \in \mathbb{Q}_p$.

Proof. Let $l = |x| + |y|$. Apply cell decomposition theorem to $\phi(x;y)$ to obtain $\mathscr{D}^l$, a collection of l-cells. Let $\mathscr{D}^{l-1}$ be a collection $l-1$ of bases of cells in $\mathscr{D}^l$. Similarly, construct by induction $\mathscr{D}^i$ for each $0 \leq j < l$, where $\mathscr{D}_j$ is a collection of j-cells which are the bases of cells in $\mathscr{D}_{j+1}$. Let $\mathscr{D} = \bigcup \mathscr{D}_j$. Choose n, m large enough to cover all n', m' that come up in the cells for $Q_{n',m'}$. Choose λ_k to go over all the cosets of $Q_{n,m}$. Let $q_i(x,y)$ enumerate all of the polynomials $a_1(\bar{x}), a_2(\bar{x}), t - c(\bar{x})$ that show up in the cells of $\mathscr{D}$. Those are all polynomials of degree ≤ 1 in variables x, y. We can split each of them as $q_i(x,y) = p_i(x) - c_j(y)$ where the constant term goes into c_j. This gives us the appropriate finite collection of formulas Ψ. From cell decomposition it is easy to see that when a, a' have the same Ψ-type, then they would have they have the same ϕ-type. Thus ϕ can be written as a boolean combination of formulas from Ψ. $\square$

Lemma 3.2. *If ϕ can be written as a Boolean combination of formulas from Ψ then*

$$\mathrm{vc}(\Psi) \leq n \implies \mathrm{vc}(\phi) \leq n$$

If a, a' have the same Ψ-type over B, then they have the same ϕ-type over B, where B is some parameter set. Therefore the number of ϕ-types is bounded by the number of Ψ-types. The bound follows from lemma **??**

Therefore to show that

Definition 3.3. A tuple $p \in \mathbb{Q}_p^{|x|}$ can be viewed as a vector $\vec{p}$, treating $\mathbb{Q}_p^{|x|}$ as a vector space over $\mathbb{Q}_p$.

We may rewrite our collection of formulas $\Psi(x,y)$ as

$$\operatorname{val}(\vec{p}_i \cdot \vec{x}) - c_i(y) < \operatorname{val}(\vec{p}_j \cdot \vec{x}) - c_j(y) \qquad i, j \in I$$

$$\operatorname{val}(\vec{p}_i \cdot \vec{x}) - c_i(y) \in \lambda_k Q \qquad i \in I, k \in K$$

Lemma 3.4. *Suppose we have a finite collection of vectors $\{\vec{p}_i\}_{i\in I}$ with each $\vec{p}_i \in \mathbb{Q}_p^{|x|}$. Suppose $J \subset I$ and $i \in I$ satisfy*

$$\vec{p}_i \in \operatorname{span}\{\vec{p}_j\}_{j\in J},$$

and we have $\vec{x} \in \mathbb{Q}_p^{|x|}, \alpha \in \mathbb{Z}$ with

$$\operatorname{val}(\vec{p}_j \cdot \vec{x}) > \alpha \text{ for all } j \in J$$

Then

$$\operatorname{val}(\vec{p}_i \cdot \vec{x}) > \alpha - \gamma$$

for some $\gamma \in \mathbb{N}$. Moreover γ can be chosen independently from $J, j, \vec{x}, \alpha$ depending only on $\{\vec{p}_i\}_{i\in I}$.

Proof. Fix i, J satisfying the conditions of the lemma. For some $c_j \in \mathbb{Q}_p$ for $j \in J$ we have

$$\vec{p}_i = \sum_{j\in J} c_j \vec{p}_j,$$

hence

$$\vec{p}_i \cdot \vec{x} = \sum_{j \in J} c_j \vec{p}_j \cdot \vec{x}.$$

We have

$$\operatorname{val}(c_j \vec{p}_j \cdot \vec{x}) = \operatorname{val}(c_j) + \operatorname{val}(\vec{p}_j \cdot \vec{x}) > \operatorname{val}(c_j) + \alpha.$$

Let $\gamma = \max(0, \min - \operatorname{val}(c_j))$. Then we have

$$\operatorname{val}(c_j \vec{p}_j \cdot \vec{x}) > \alpha - \gamma \qquad \text{for all } j \in J$$

$$\sum_{j \in J} c_j \vec{p}_j \cdot \vec{x} > \alpha - \gamma$$

This shows that we can pick such γ for a given choice of i, J, but independent from $\alpha, \vec{x}$. To get a choice independent from i, J, go over all such eligible choices (i ranges over I and J ranges over subsets of I), pick γ for each, and then take the maximum of those values. □

Definition 3.5. For $c \in \mathbb{Q}_p, \alpha \in \mathbb{Z}$ we define an open ball

$$B(c, \alpha) = \{c' \in \mathbb{Q}_p \mid \operatorname{val}(c' - c) \leq \alpha\}$$

Definition 3.6. Suppose we have a finite $T \subset \mathbb{Q}_p$. We view it as a tree as follows. Branches through the tree are elements of T. With this tree we associate open balls $B(t_1, \operatorname{val}(t_1 - t_2))$ for all $t_1, t_2 \in T$. An interval is two balls $B(t_1, v_1) \supset B(t_2, v_2)$ with no balls in between. An element $a \in \mathbb{Q}_p$ belongs to this interval if $a \in B(t_1, v_1) \backslash B(t_2, v_2)$. There are at most $2|T|$ different intervals and they partition the entire space.

Fix a parameter set B of size N.

Consider a tree $T = \{c_i(b) \mid b \in B, i \in I\}$ It has at most $O(N) = N \cdot |I|$ many intervals. Denote the set of all intervals as Pt. For the remainder of the paper we work with this tree.

Definition 3.7. Let $c \in \mathbb{Q}_p$. It lies in the tree in one of the unique intervals $B(c_L, \alpha_L) \backslash B(c_U, \alpha_U)$. Define $F(c)$, the floor of c to be α_L.

Definition 3.8. We say $x, x' \in \mathbb{Q}_p$ have the same tree type if

- $\operatorname{val}(x - c_i(b)) < \operatorname{val}(x - c_j(b))$ iff $\operatorname{val}(x' - c_i(b)) < \operatorname{val}(x' - c_j(b))$ for all $i, j \in I, b \in B$
- $x + c_i(b)$ is in the same Q-coset as $x' + c_i(b)$ for all $i \in I, b \in B$

Lemma 3.9. *Let $a, a' \in \mathbb{Q}_p^{|x|}$. If $p_i(a), p_i(a')$ have the same tree type for all $i \in I$, then a, a' have the same Ψ-type.*

Proof. Clear from the construction. □

Definition 3.10. For $c \in \mathbb{Q}_p$ and $\alpha, \beta \in \mathbb{Z}$ let $c \restriction [\alpha, \beta] \in (\mathbb{Z}/p\mathbb{Z})^{\beta - \alpha}$ be the record of coefficients of c for the valuations between α, β. More precisely write c in its power series form

$$c = \sum_{\gamma \in Z} c_\gamma p^\gamma \text{ with } c_\gamma \in \mathbb{Z}/p\mathbb{Z}$$

Then $c \restriction [\alpha, \beta]$ is just $(c_\alpha, c_{\alpha+1}, \ldots c_\beta)$.

The following lemma is an adaptation of lemma 7.4 in [1].

Lemma 3.11. *For n, m there exists $D = D(n, m) \in \mathbb{Z}$ such that for any $x, y, a \in \mathbb{Q}_p$ if*

$$\operatorname{val}(x - c) = \operatorname{val}(y - c) < \operatorname{val}(x - y) - D$$

then $x - c, y - c$ are in the same coset of $Q_{n,m}$.

Proof. Define that $a, b \in \mathbb{Q}_p$ are similar if $\operatorname{val} a = \operatorname{val} b$ and

$$a \restriction [\operatorname{val} a, \operatorname{val} a + (m+n)] = b \restriction [\operatorname{val} b, \operatorname{val} b + (m+n)]$$

If a, b are similar then

$$a \in Q_{n,m} \leftrightarrow b \in Q_{n,m}$$

Moreover for any $\lambda \in \mathbb{Q}_p$, if a, b are similar we would also have $a/\lambda, b/\lambda$ are similar. Thus if a, b are similar, then they belong in the same coset of $Q_{n,m}$. If we pick $D = n + m$ then conditions of the lemma force $x - c, y - c$ to be similar. $\square$

The following construction is along the lines of lemmas 7.3, 7.5 of [1].

Definition 3.12. For two balls $B(a, \alpha), B(b, \beta)$ let $\gamma = \min(\alpha, \beta, \mathrm{val}(a-b))$. Define the distance between those two balls to be $|\alpha - \gamma| + |\beta - \gamma|$. In $\mathbb{Q}_p$ value group is discrete and residue field is finite, so there are finitely many balls at a fixed distance from a given ball. Near balls of $B(a, \alpha)$ are defined to be balls with distance $\mathcal{D}$ from $B(a, \alpha)$. Enumerate those as:

$$B_1(a, \alpha), B_2(c, \alpha), \ldots B_{N_D}(a, \alpha)$$

Near balls partition the space

$$\{b \in \mathbb{Q}_p \mid |\mathrm{val}(a - b) - \alpha| \leq D\}$$

Definition 3.13. Let $c \in \mathbb{Q}_p$. It lies in our tree in one of the intervals $B(c_L, \alpha_L) \backslash B(c_U, \alpha_U)$. Suppose c lies in one of the near balls of $B(c_L, \alpha_L)$ or $B(c_U, \alpha_U)$. Then define its interval type to be the index of that near ball. Otherwise define its interval type to be the coset of $c - c_U$ of Q. Denote the space of all the possible branch types Bt.

Lemma 3.14. *If a, a' are in the same interval and have the same interval type then they have the same tree type.*

Proof. First part of the tree type definition is satisfied as a, a' are in the same interval, so we only need to demonstrate that the corresponding Q-cosets match. Pick any element of our tree $c_i(b)$. We want to show that $a - c_i(b), a' - c_i(b)$ are in the same Q-coset.

Suppose a is in one of the near balls. As a' has the same interval type, it has to be in the same near ball. By definition of the near ball we then have $\mathrm{val}(a - c_i(b)) = \mathrm{val}(a' - c_i(b)) < \mathrm{val}(a - a') - D$. Thus by Lemma 3.11 we have $a - c_i(b), a' - c_i(b)$ in the same Q-coset.

Now, suppose both a, a' aren't in any near balls. Label their interval as $B(c_L, \alpha_L) \backslash B(c_U, \alpha_U)$. Then we have

$$\alpha_L + D < \mathrm{val}(a - c_U) < \alpha_U - D$$

$$\alpha_L + D < \mathrm{val}(a' - c_U) < \alpha_U - D$$

as otherwise one (both) of them would be in one of the near balls. We have either $\mathrm{val}(c_U - c_i(b)) \geq \alpha_U$ or $\mathrm{val}(c_U - c_i(b)) \leq \alpha_L$ as otherwise it would contradict the definition of an interval.

Suppose it is the first case $\mathrm{val}(c_U - c_i(b)) \geq \alpha_U$. Then

$$\mathrm{val}(a - c_i(b)) = \mathrm{val}(a - c_U) < \alpha_U - D \leq \mathrm{val}(c_U - c_i(b)) - D$$

so by Lemma 3.11 we have $a - c_i(b), a - c_U$ are in the same Q-coset. By a parallel argument we have $a' - c_i(b), a' - c_U$ are in the same Q-coset. As we are assuming a, a' have the same tree type it implies that $a - c_U, a' - c_U$ are in the same Q-coset. Thus by transitivity we get that $a - c_i(b), a' - c_i(b)$ are in the same Q-coset.

For the second case, suppose $\mathrm{val}(c_U - c_i(b)) \leq \alpha_L$. Then

$$\mathrm{val}(a - c_i(b)) = \mathrm{val}(c_U - c_i(b)) \leq \alpha_L < \mathrm{val}(a - c_U) - D$$

so by Lemma 3.11 we have $a - c_i(b), c_U - c_i(b)$ are in the same Q-coset. By a parallel argument we have $a' - c_i(b), c_U - c_i(b)$ are in the same Q-coset. Thus by transitivity we get that $a - c_i(b), a' - c_i(b)$ are in the same Q-coset. □

4. Main Proof

Fix γ corresponding to $\{\vec{p}_i\}_{i \in I}$ according to Lemma 3.4.

Definition 4.1. Denote $\mathbb{Z}/p\mathbb{Z}^{\gamma}$ as Ct.

Definition 4.2. Let $f : \mathbb{Q}_p^{|x|} \longrightarrow \mathbb{Q}_p^{I}$ with $f(\bar{c}) = (p_i(\bar{c}))_{i \in I}$. Define the segment space Sg to be the image of f.

Given a tuple $(a_i)_{i \in I}$in the segment space look at the corresponding floors $\{F(a_i)\}_{i \in I}$. Those are ordered as elements of $\mathbb{Z}$. Partition the segment space by order type of $\{F(a_i)\}$. Work in a fixed partition Sg'. After relabeling we may assume that

$$F(a_1) \geq F(a_2) \geq \dots$$

Consider the (relabeled) sequence of vectors $\vec{p}_1, \vec{p}_2, \dots, \vec{p}_I$. There is a unique subset $J \subset I$ such that all vectors with indices in J are linearly independent, and all vectors with indices outside of J are a linear combination of preceding vectors. For any index $i \in I$ we call it independent if $i \in J$ and we call it dependent otherwise.

Now, we define the following function

$$g : \mathrm{Sg}' \longrightarrow \mathrm{Bt}^{I} \times \mathrm{Pt}^{J} \times \mathrm{Ct}^{I-J}$$

Let $\bar{a} = (a_i)_{i \in I} \in \mathrm{Sg}'$. To define $g(\bar{a})$ we need to specify where it maps $\bar{a}$ in each individual component of the product.

For all a_i record its interval type $\in$ Bt, giving the first component.

For a_j with $j \in J$, record the interval of a_j, giving the second component.

For the third component do the following computation. Pick a_i with i dependent. Let j be the largest independent index with $j < i$. Record $a_i \restriction [F(a_j) - \gamma, F(a_j)]$.

Lemma 4.3. *For $\bar{a}, \bar{a}' \in \mathrm{Sg}'$ if $g(\bar{a}) = g(\bar{a}')$ then a_i, a_i' have the same tree type for all $i \in I$.*

Proof. For each i we show that a_i, a_i' are in the same interval and have the same interval type, so the conclusion follows by Lemma 3.14. Bt records the interval type of each element, so if $g(\bar{a}) = g(\bar{a}')$ then a_i, a_i' have the same interval type for all $i \in I$. Thus it remains to show that a_i, a_i' lie in the same interval for all $i \in I$. Suppose i is an independent index. Then by construction, Pt records the interval for a_i, a_i', so those have to belong to the same interval. Now suppose i is dependent. Pick the largest $j < i$ such that j is independent. We have $F(a_i) \leq F(a_j)$ and $F(a_i') \leq F(a_j')$. Moreover $F(a_j) = F(a_j')$ as they are mapped to the same interval (using the earlier part of the argument as j is independent).

Claim 4.4. $\mathrm{val}(a_i - a_i') > F(a_j) - \gamma$

Proof. Let $\vec{x}, \vec{x}' \in \mathbb{Q}_p^{|x|}$ be some elements with

$$\vec{p}_k \cdot \vec{x} = a_k$$

$$\vec{p}_k \cdot \vec{x}' = a_k' \text{ for all } k \in I$$

It is always possible to do that as $\bar{a}, \bar{a}' \in \mathrm{Sg}'$. Let J' be the set of the independent indices less than i. We have

$$\mathrm{val}(a_k - a_k') > F(a_k) \text{ for all } k \in J'$$

as for the independent indices a_k, a_k' lie in the same interval.

$$\mathrm{val}(a_k - a_k') > F(a_j) \text{ for all } k \in J' \text{ by monotonicity of } F(a_k)$$

$$\mathrm{val}(\vec{p}_k \cdot \vec{x} - \vec{p}_k \cdot \vec{x}') > F(a_j) \text{ for all } k \in J'$$

$$\mathrm{val}(\vec{p}_k \cdot (\vec{x} - \vec{x}')) > F(a_j) \text{ for all } k \in J'$$

J' and i match the requirements of Lemma 3.4 so we conclude

$$\mathrm{val}(\vec{p}_i \cdot (\vec{x} - \vec{x}')) > F(a_j) - \gamma$$

$$\mathrm{val}(\vec{p}_i \cdot \vec{x} - \vec{p}_i \cdot \vec{x}') > F(a_j) - \gamma$$

$$\mathrm{val}(a_i - a_i')) > F(a_j) - \gamma$$

as needed, finishing the proof of the claim. □

Additionally a_i, a_i' have the same image in Ct component, so we have

$$\mathrm{val}(a_i - a_i') > F(a_j)$$

As $F(a_i) \leq F(a_j)$, a_i, a_i' have to lie in the same interval. □

Corollary 4.5. *$\Psi(x, y)$ has VC-density $\leq |x|$*

Proof. Suppose we have $c, c' \in \mathbb{Q}_p^{|x|}$ such that $f(c), f(c')$ are in the same partition and $g(f(c)) = g(f(c'))$. Then by the previous lemma $p_i(c)$ has the same tree type as $p_i(c')$ for all $i \in I$. Then by Lemma 3.9 c, c' have the same Ψ-type. Thus the number of possible Ψ-types is bounded by the size of the range of g times the number of possible partitions

$$(\text{number of partitions}) \cdot |Bt|^{|I|} \cdot |Pt|^{|J|} \cdot |Ct|^{|I-J|}$$

We have

$$|\operatorname{Bt}| = N_D + \text{number of cosets of } Q |\operatorname{Pt}| \leq N \cdot I^2 \text{ (the only component dependent on } N)$$

$$|\operatorname{Ct}| = p^{\gamma}$$

and there are at most $|I|!$ many partitions of Sg. This gives us a bound

$$|I|! \cdot |Bt|^{|I|} \cdot (N \cdot |I|^2)^{|J|} \cdot p^{\gamma|I-J|} = O(N^{|J|})$$

Every p_i is an element of a $|x|$-dimensional vector space, so there can be at most $|x|$ many independent vectors. Thus we have $|J| \leq |x|$ and the bound follows. □

Corollary 4.6. *In the language $\mathcal{L}_{aff}$ we have $\mathrm{vc}(n) = n$.*

Proof. Previous lemma implies that $\mathrm{vc}(\phi) \leq \mathrm{vc}(\Psi) \leq |x|$. As choice of ϕ was arbitrary, this implies that VC-density of any formula is bounded by the arity of x. $\square$
